National Centers for Environmental Prediction**

## CLIMATE DIAGNOSTICS BULLETIN

### CLIMATE PREDICTION CENTER Attn: Climate Diagnostics Bulletin W/NP52, Room 605, WWBG Camp Springs, MD 20746-4304

**Chief Editor:** Gerald D. Bell

**Editors:** Wei Shi, Michelle L'Heureux, and Michael Halpert

**Bulletin Production:** Wei Shi

**External Collaborators:**

Center for Ocean-Atmospheric Prediction Studies (COAPS)  
Cooperative Institute for Research in the Atmosphere (CIRA)  
Earth & Space Research  
International Research Institute for Climate and Society (IRI)  
Joint Institute for the Study of the Atmosphere and Ocean (JISAO)  
Lamont-Doherty Earth Observatory (LDEO)  
NOAA-CIRES, Climate Diagnostics Center  
NOAA-AOML, Atlantic Oceanographic and Meteorological Laboratory  
NOAA-NESDIS-STAR, Center for Satellite Applications and Research  
NOAA-NDBC, National Data Buoy Center  
Scripps Institution of Oceanography

**Software:** Most of the bulletin figures generated at CPC are created using the Grid Analysis and Display System (GrADS).

**- Climate Diagnostics Bulletin available on the World Wide Web**

The CDB is available on the World Wide Web. The address of the online version of the CDB is:

**<http://www.cpc.ncep.noaa.gov/products/CDB>**

If you have any problems accessing the bulletin, contact Dr. Wei Shi by E-mail:

## **Tropical Highlights - December 2012**

During December 2012, the sea surface temperatures (SSTs) remained near average across the central and east-central equatorial Pacific, but colder-than-average over the far eastern equatorial Pacific (Fig. T18, Table T2). The latest monthly Niño indices were  $-0.1^{\circ}\text{C}$  for the Niño 3.4 region and  $-0.9^{\circ}\text{C}$  for the Niño 1+2 region (Table T2, Fig. T5). Consistent with these conditions, the depth of the oceanic thermocline (measured by the depth of the 20C isotherm) remained near average across the central and east-central equatorial Pacific (Figs. T15, T16).

The equatorial low-level easterly trade winds remained slightly enhanced over the western equatorial Pacific during December, and were near-average across the central and east-central equatorial Pacific (Table T1, Fig. T20). This pattern is largely consistent with continued ENSO-neutral conditions. Suppressed convection was seen over the western and central equatorial Pacific (Figs. T25, E3). Collectively, these oceanic and atmospheric anomalies reflect ENSO-neutral conditions.

For the latest status of the ENSO cycle see the ENSO Diagnostic Discussion at:  
[http://www.cpc.ncep.noaa.gov/products/analysis\\_monitoring/enso\\_advisory/index.html](http://www.cpc.ncep.noaa.gov/products/analysis_monitoring/enso_advisory/index.html)

TABLE T1 - Atmospheric index values for the most recent 12 months. Indices are standardized by the mean annual standard deviation, except for the Tahiti and Darwin SLP anomalies which are in units of hPa. Positive (negative) values of 200-hPa zonal wind index imply westerly (easterly) anomalies. Positive (negative) values of 850-hPa zonal wind indices imply easterly (westerly) anomalies. Anomalies are departures from the 1981-2010 base period means.

TABLE T2. Mean and anomalous sea surface temperature (°C) for the most recent 12 months. Anomalies are departures from the 1981–2010 adjusted OI climatology (Smith and Reynolds 1998, *J. Climate*, **11**, 3320–3323).

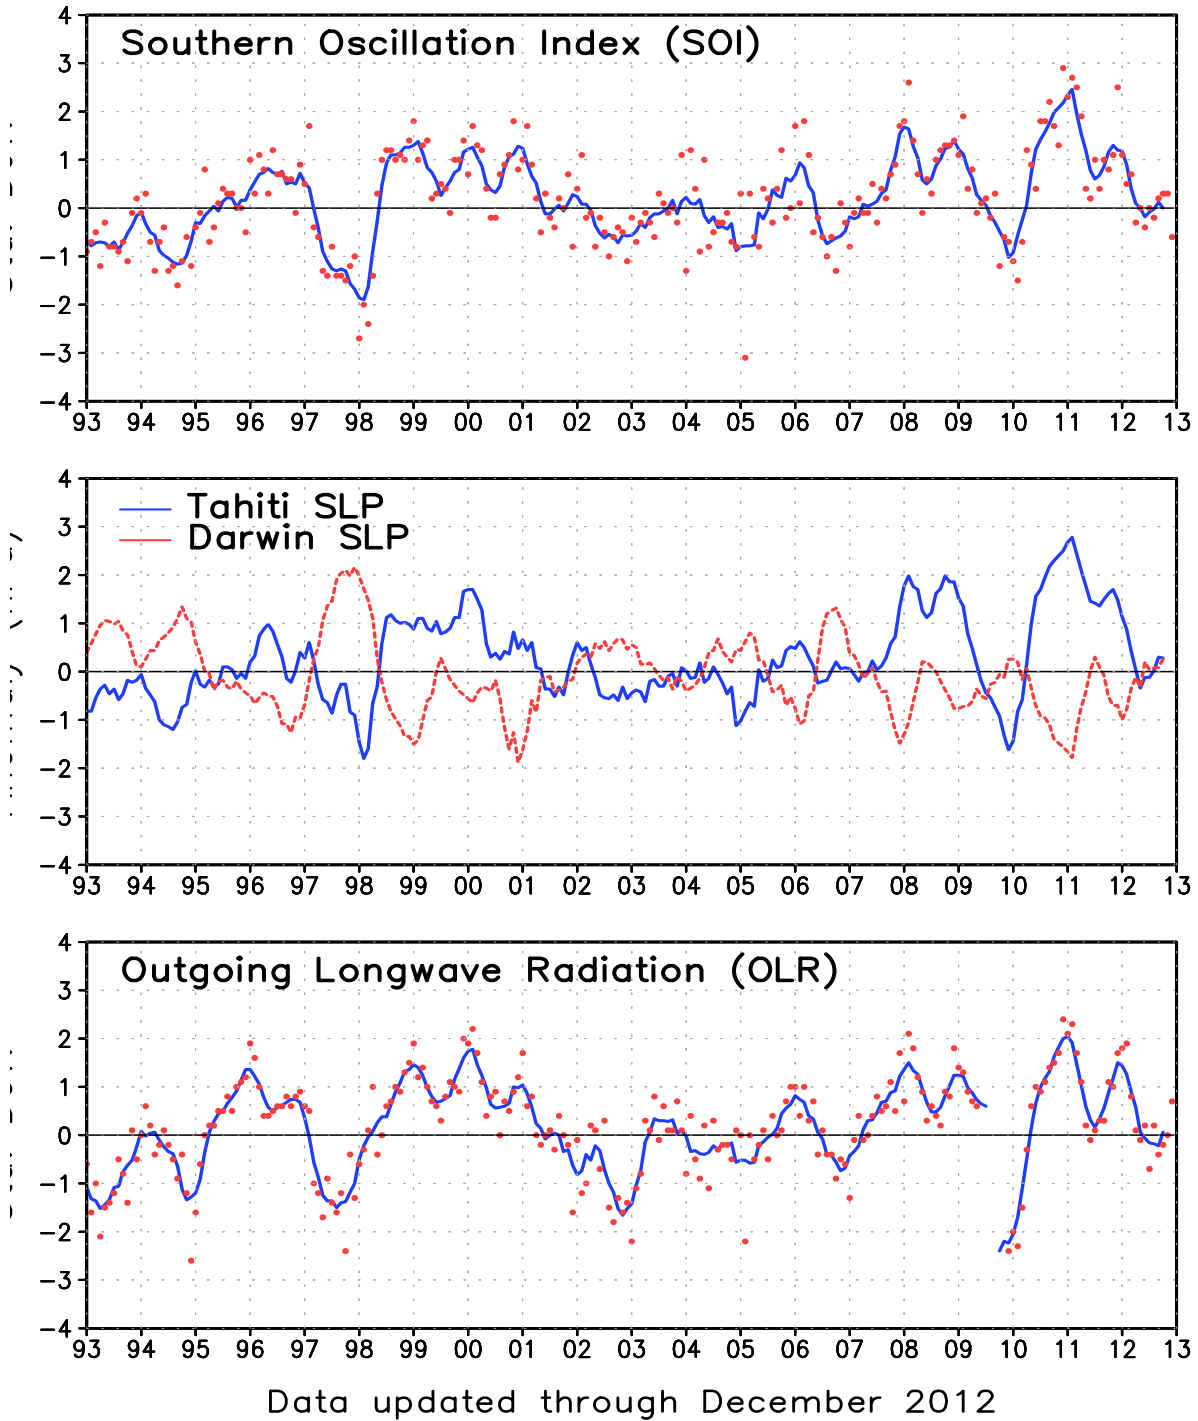

FIGURE T1. Five-month running mean of the Southern Oscillation Index (SOI) (top), sea-level pressure anomaly (hPa) at Darwin and Tahiti (middle), and outgoing longwave radiation anomaly (OLR) averaged over the area 5N-5S, 160E-160W (bottom). Anomalies in the top and middle panels are departures from the 1981-2010 base period means and are normalized by the mean annual standard deviation. Anomalies in the bottom panel are departures from the 1981-2010 base period means. Individual monthly values are indicated by “x”s in the top and bottom panels. The x-axis labels are centered on July.

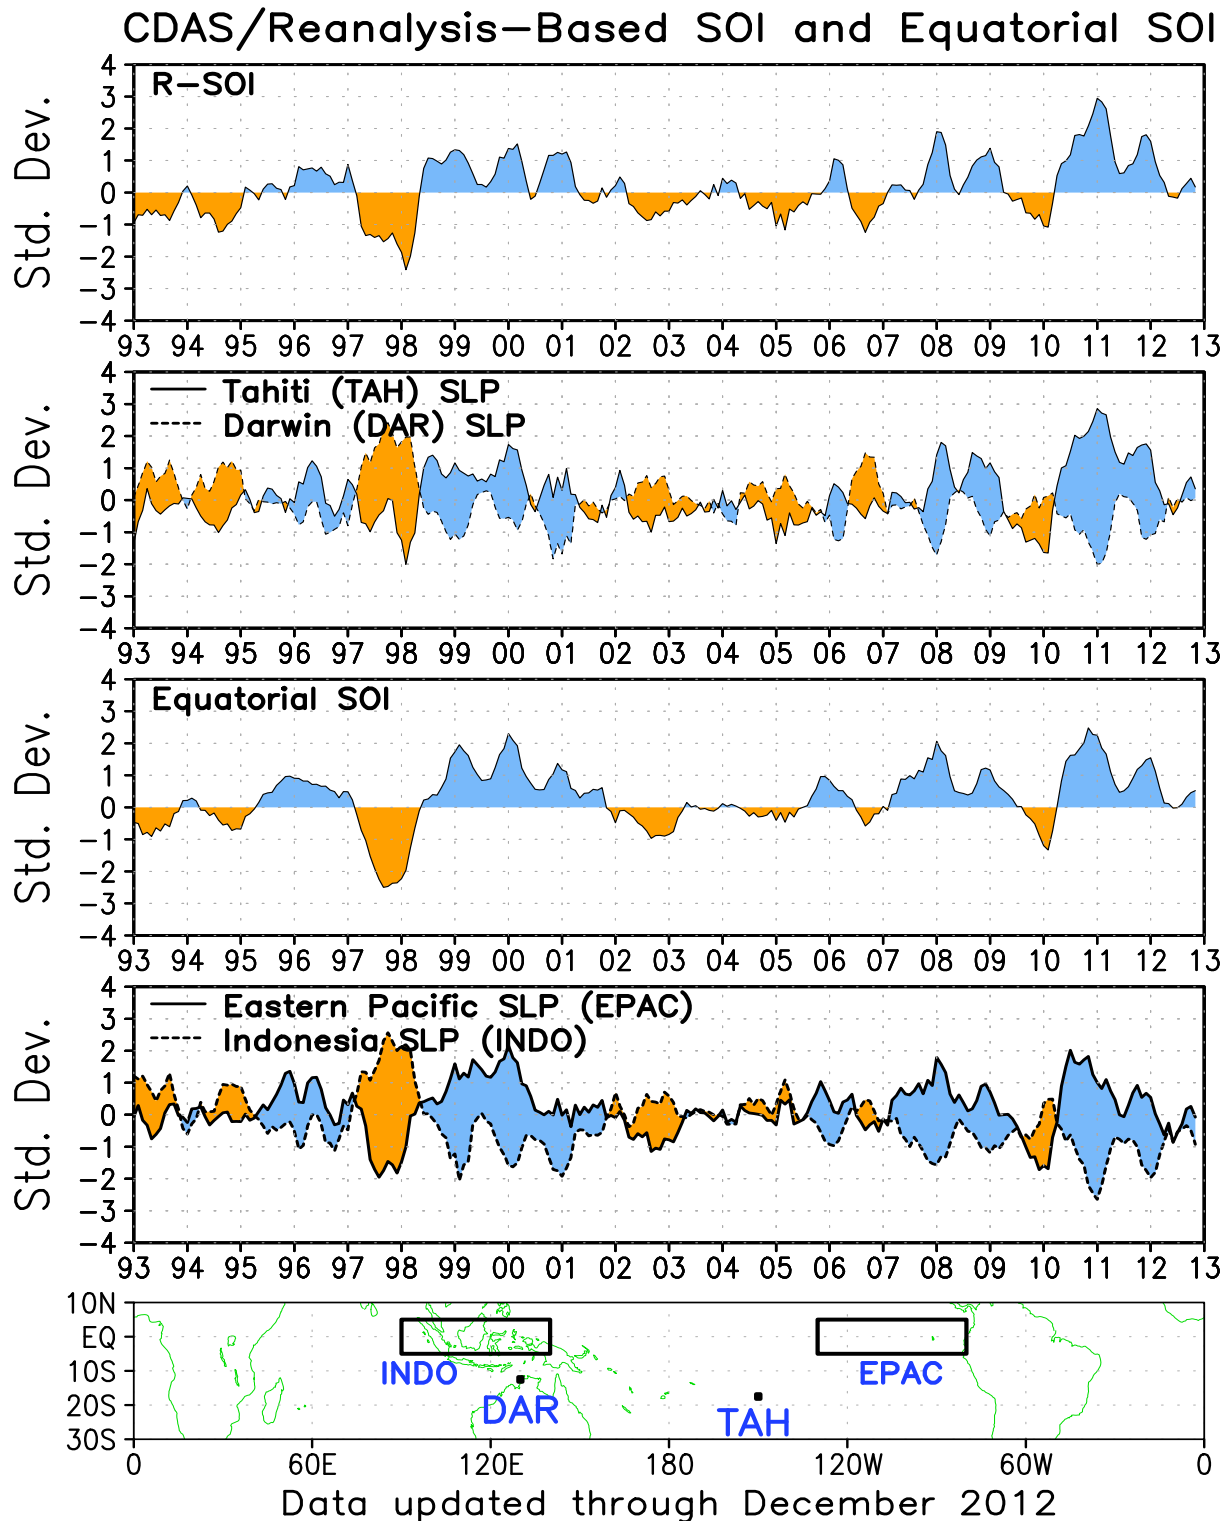

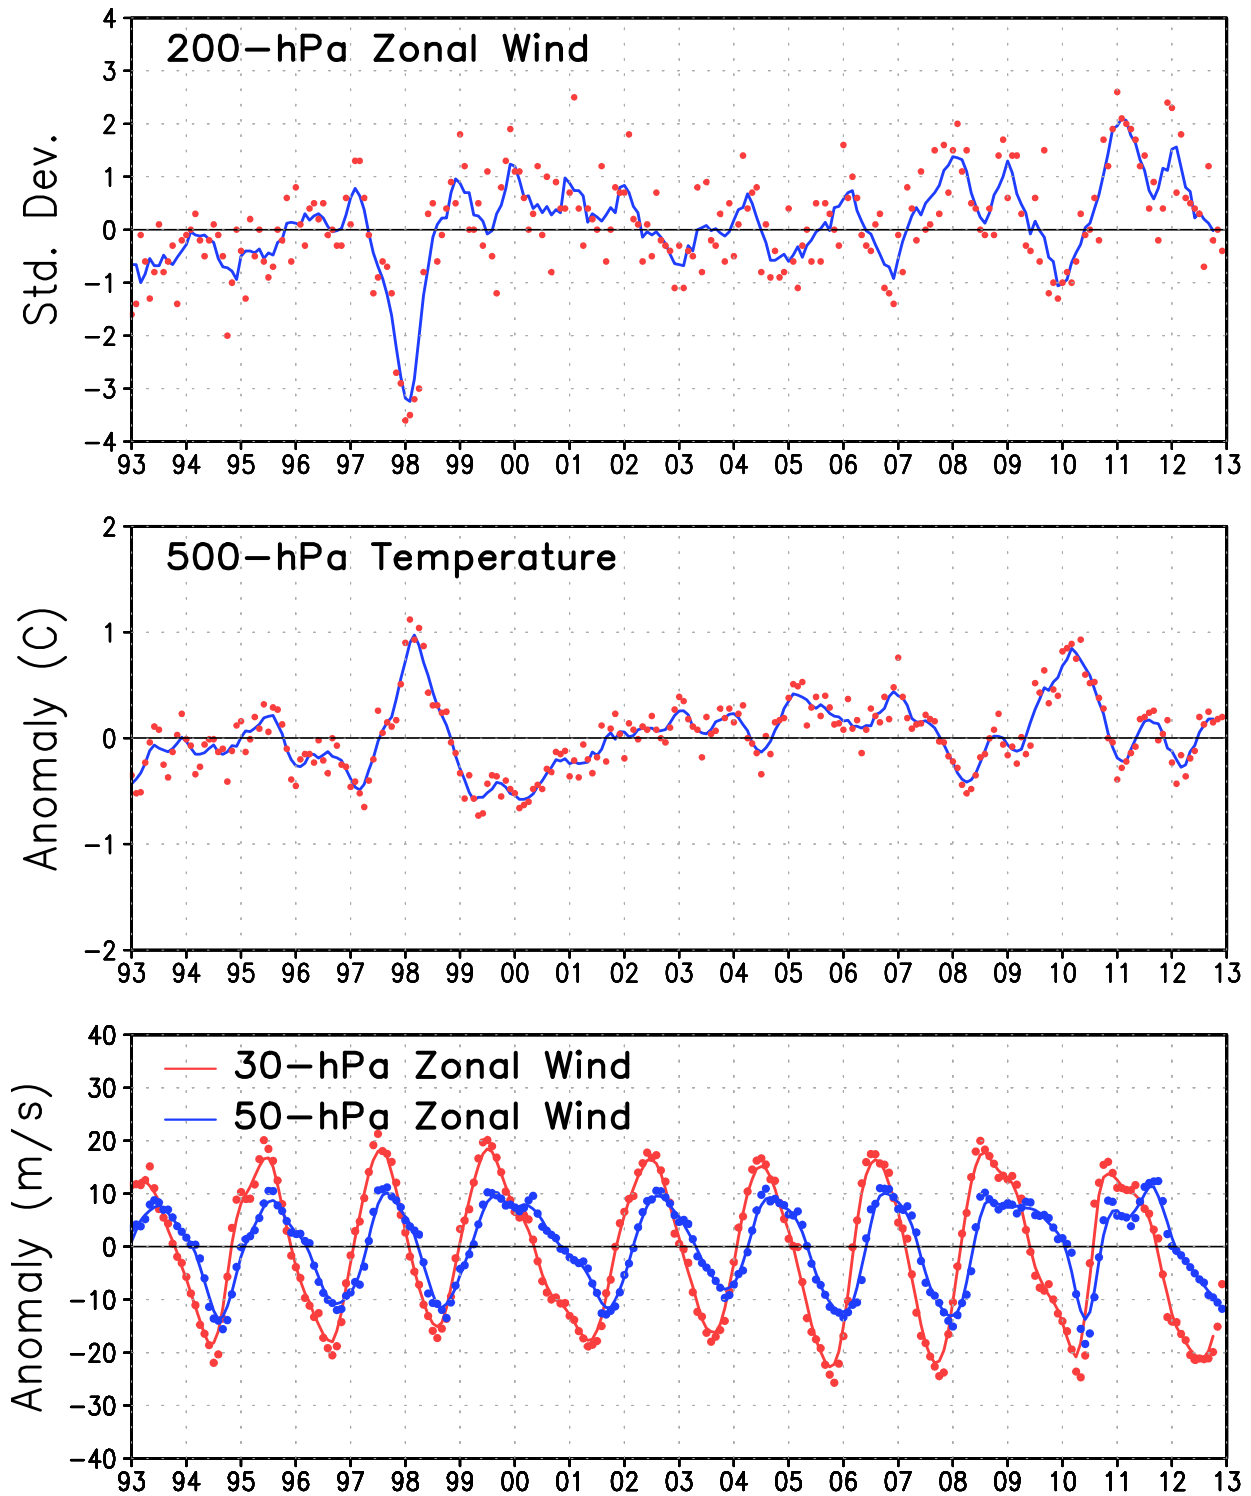

FIGURE T2. Three-month running mean of a CDAS/Reanalysis-derived (a) Southern Oscillation Index (RSOI), (b) standardized pressure anomalies near Tahiti (solid) and Darwin (dashed), (c) an equatorial SOI ([EPAC] - [INDO]), and (d) standardized equatorial pressure anomalies for (EPAC) (solid) and (INDO) (dashed). Anomalies are departures from the 1981-2010 base period means and are normalized by the mean annual standard deviation. The equatorial SOI is calculated as the normalized difference between the standardized anomalies averaged between 5°N–5°S, 80°W–130°W (EPAC) and 5°N–5°S, 90°E–140°E (INDO).

Data updated through December 2012

FIGURE T3. Five-month running mean (solid lines) and individual monthly mean (dots) of the 200-hPa zonal wind anomalies averaged over the area 5N-5S, 165W-110W (top), the 500-hPa virtual temperature anomalies averaged over the latitude band 20N-20S (middle), and the equatorial zonally-averaged zonal wind anomalies at 30-hPa (red) and 50-hPa (blue) (bottom). In the top panel, anomalies are normalized by the mean annual standard deviation. Anomalies are departures from the 1981-2010 base period means. The x-axis labels are centered on January.

Data updated through December 2012

FIGURE T4. Five-month running mean (solid line) and individual monthly mean (dots) of the standardized 850-hPa zonal wind anomaly index in the latitude belt 5N-5S for 135E-180 (top), 175W-140W (middle) and 135W-120W (bottom). Anomalies are departures from the 1981-2010 base period means and are normalized by the mean annual standard deviation. The x-axis labels are centered on January. Positive (negative) values indicate easterly (westerly) anomalies.

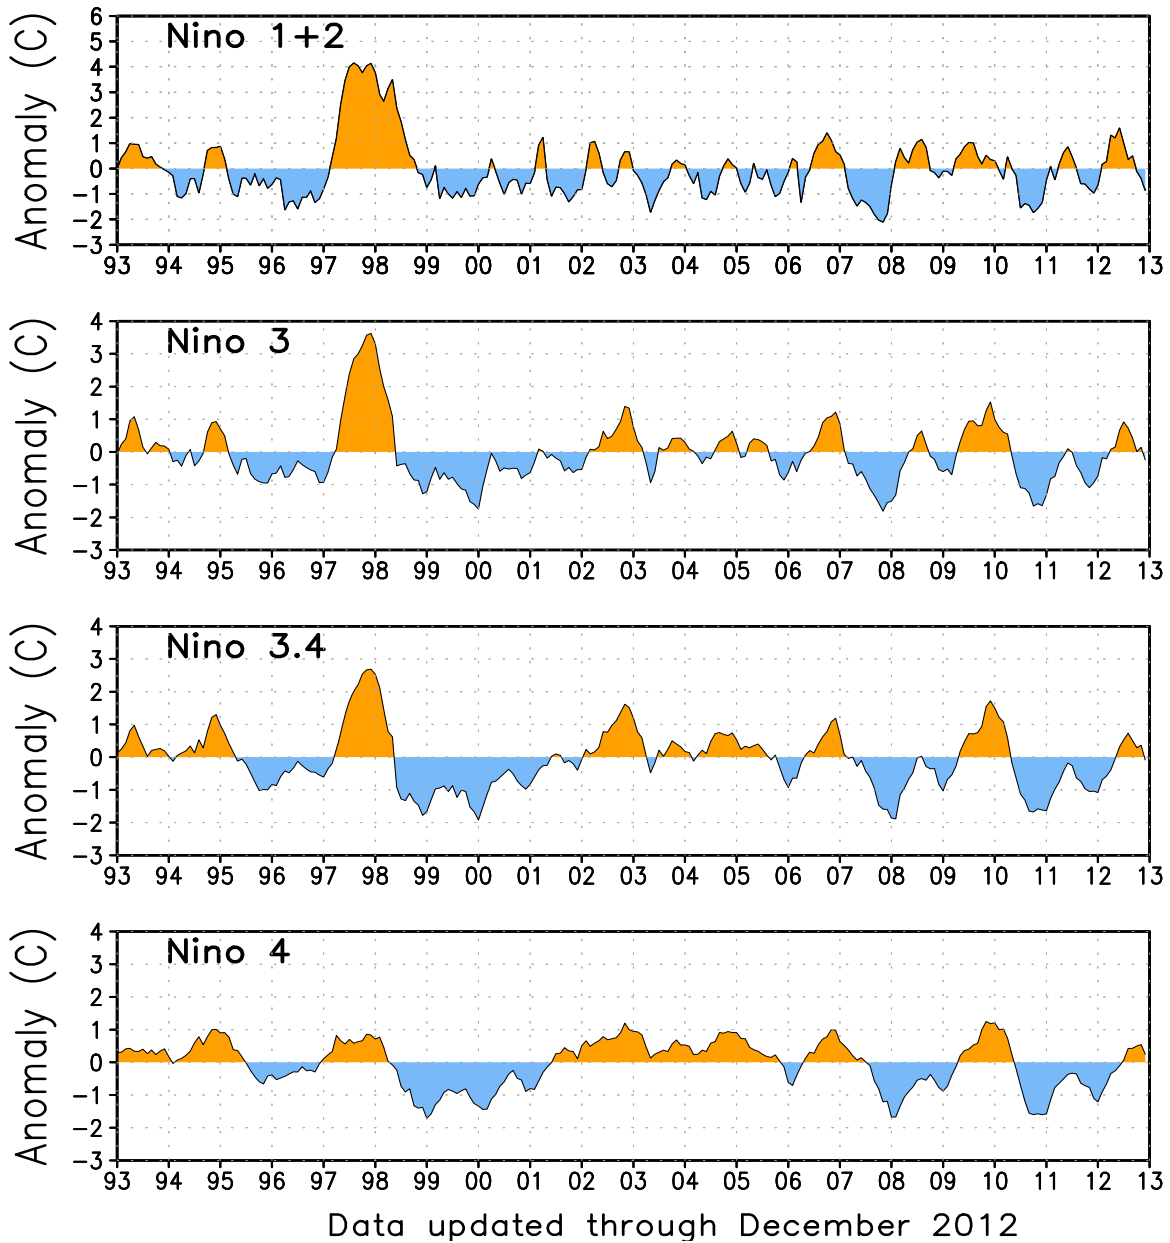

FIGURE T5. Niño region indices, calculated as the area-averaged sea surface temperature anomalies (C) for the specified region. The Niño 1+2 region (top) covers the extreme eastern equatorial Pacific between 0-10S, 90W-80W. The Niño-3 region (2nd from top) spans the eastern equatorial Pacific between 5N-5S, 150W-90W. The Niño 3.4 region (3rd from top) spans the east-central equatorial Pacific between 5N-5S, 170W-120W. The Niño 4 region (bottom) spans the date line and covers the area 5N-5S, 160E-150W. Anomalies are departures from the 1981-2010 base period monthly means (*Smith and Reynolds 1998, J. Climate, 11, 3320-3323*). Monthly values of each index are also displayed in [Table 2](#).

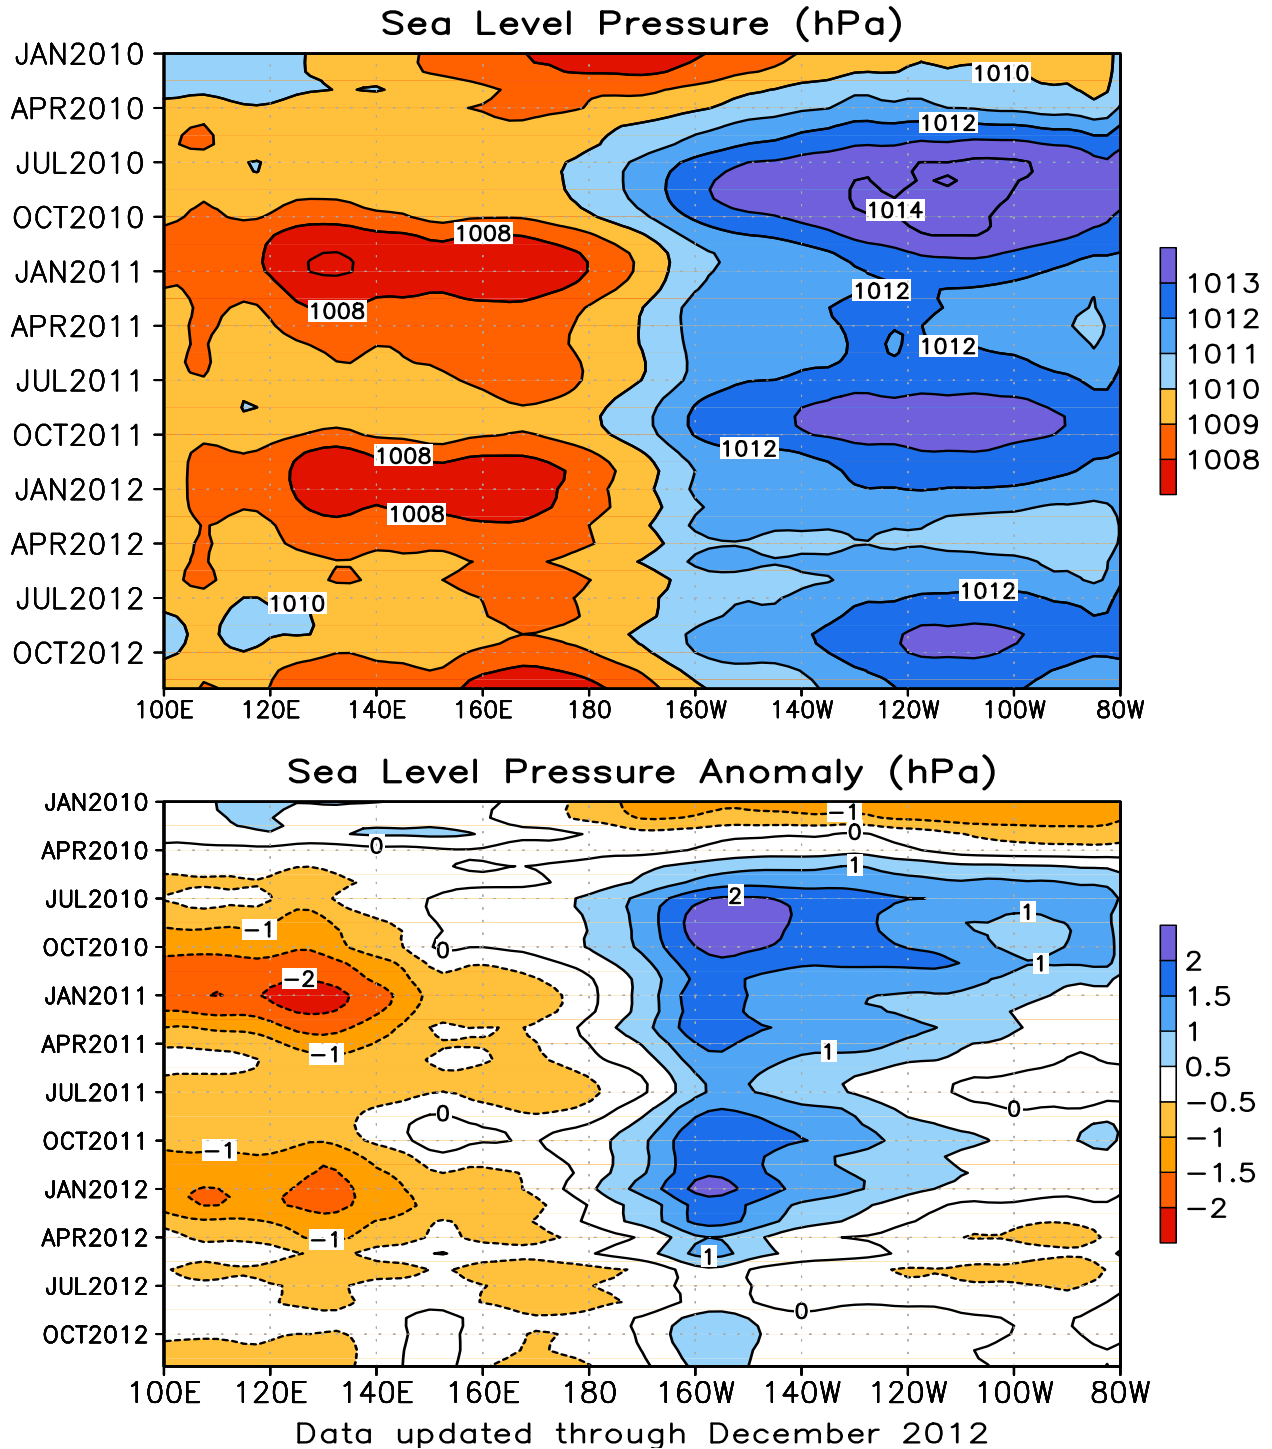

FIGURE T6. Time-longitude section of mean (top) and anomalous (bottom) sea level pressure (SLP) averaged between 5N-5S (CDAS/Reanalysis). Contour interval is 1.0 hPa (top) and 0.5 hPa (bottom). Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1981-2010 base period monthly means. The data are smoothed temporally using a 3-month running average.

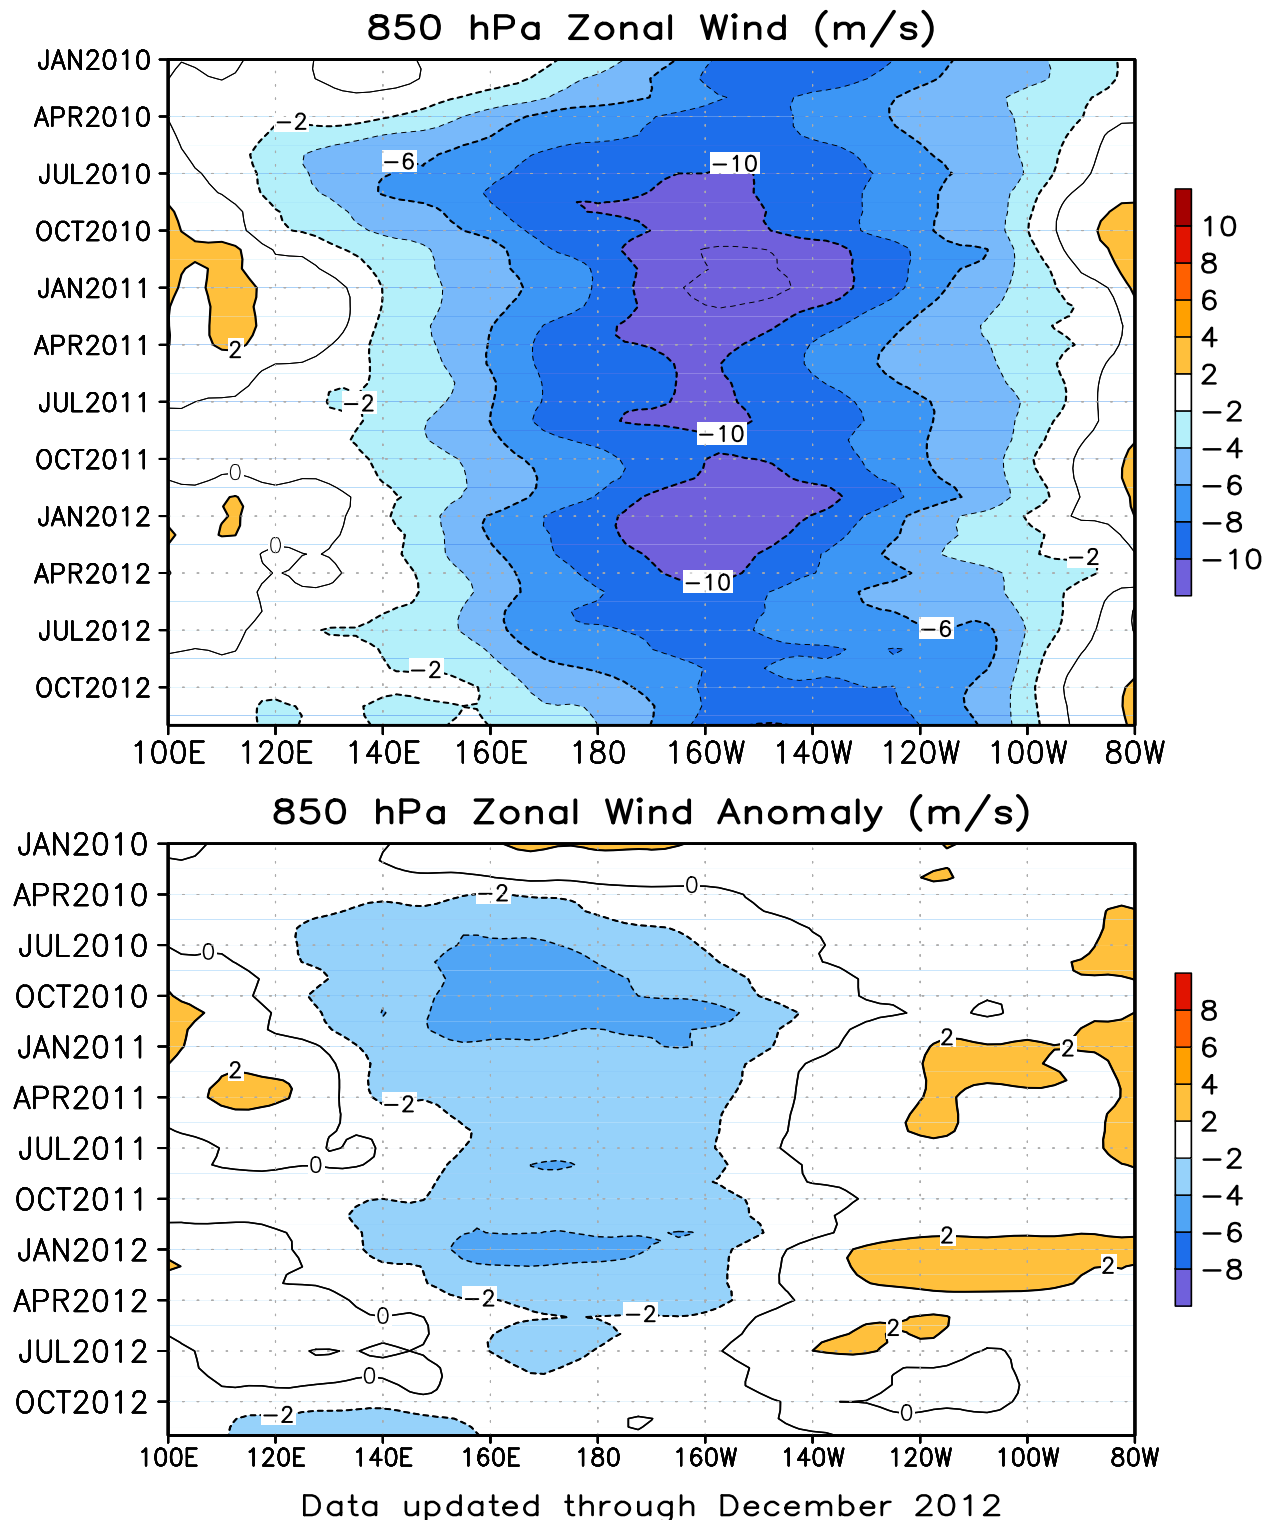

FIGURE T7. Time-longitude section of mean (top) and anomalous (bottom) 850-hPa zonal wind averaged between 5N-5S (CDAS/Reanalysis). Contour interval is  $2 \text{ ms}^{-1}$ . Blue shading and dashed contours indicate easterlies (top) and easterly anomalies (bottom). Anomalies are departures from the 1981-2010 base period monthly means. The data are smoothed temporally using a 3-month running average.

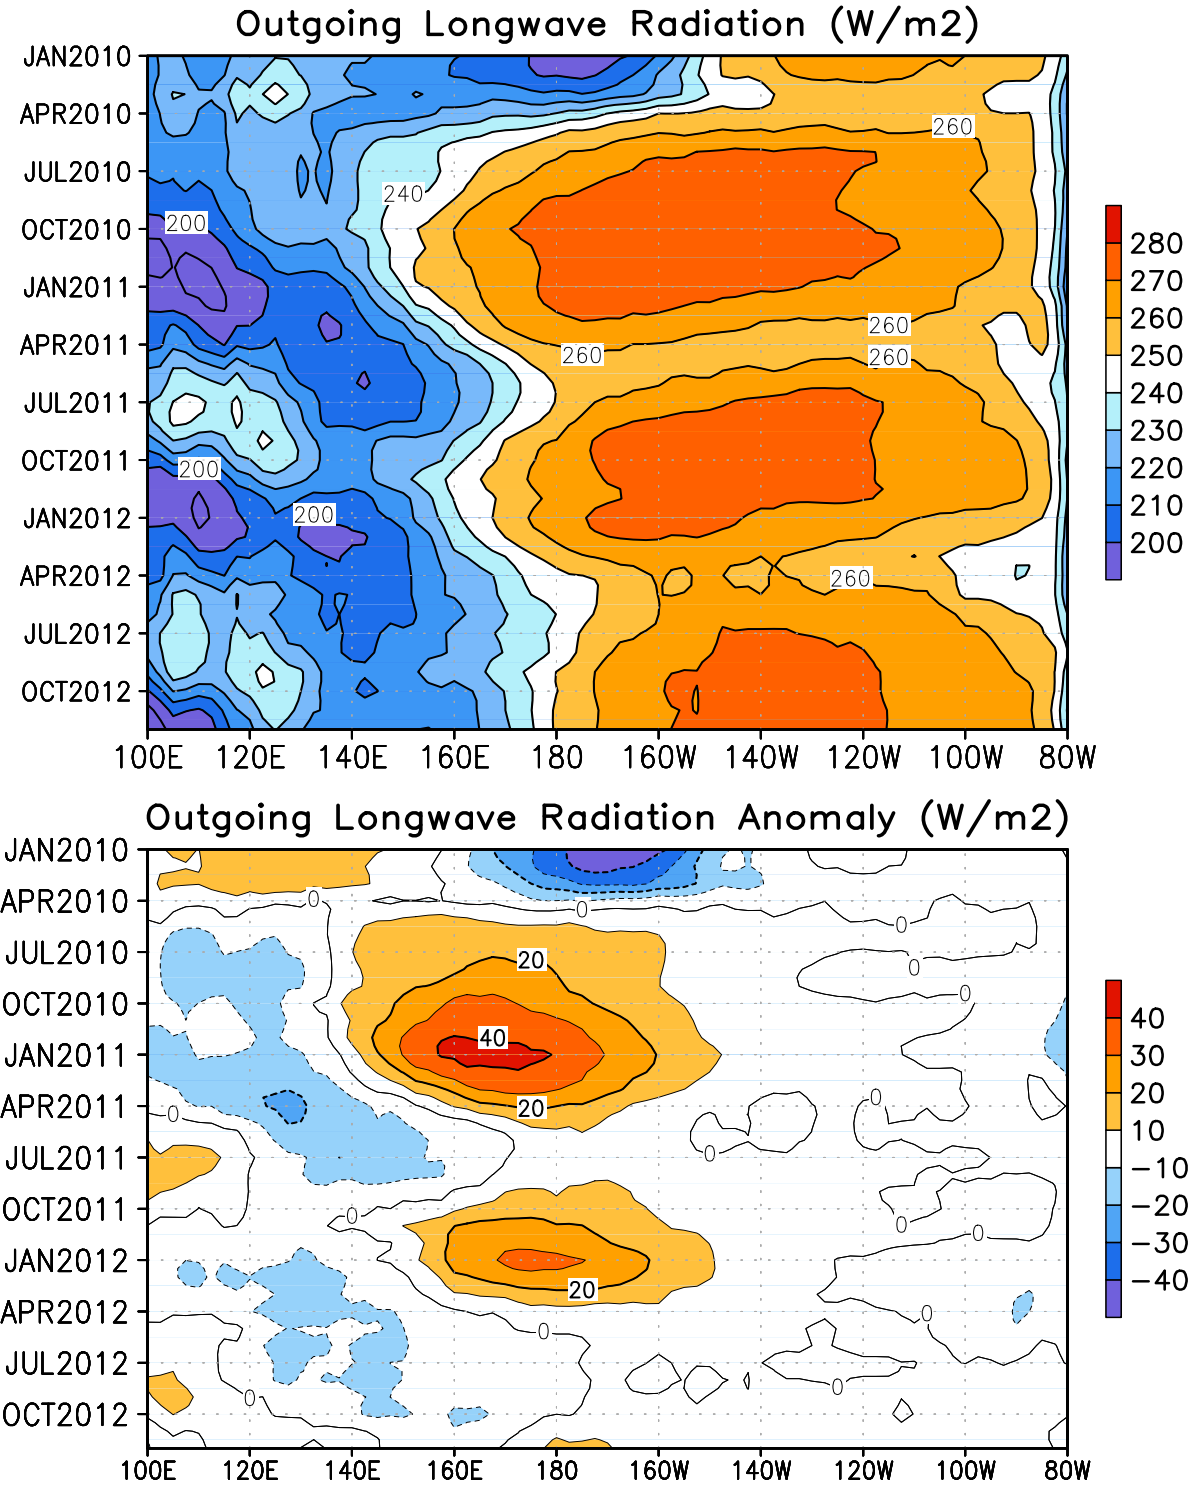

FIGURE T8. Time-longitude section of mean (top) and anomalous (bottom) outgoing longwave radiation (OLR) averaged between 5N-5S. Contour interval is 10 Wm<sup>-2</sup>. Dashed contours in bottom panel indicate negative OLR anomalies. Anomalies are departures from the 1981-2010 base period monthly means. The data are smoothed temporally using a 3-month running average.

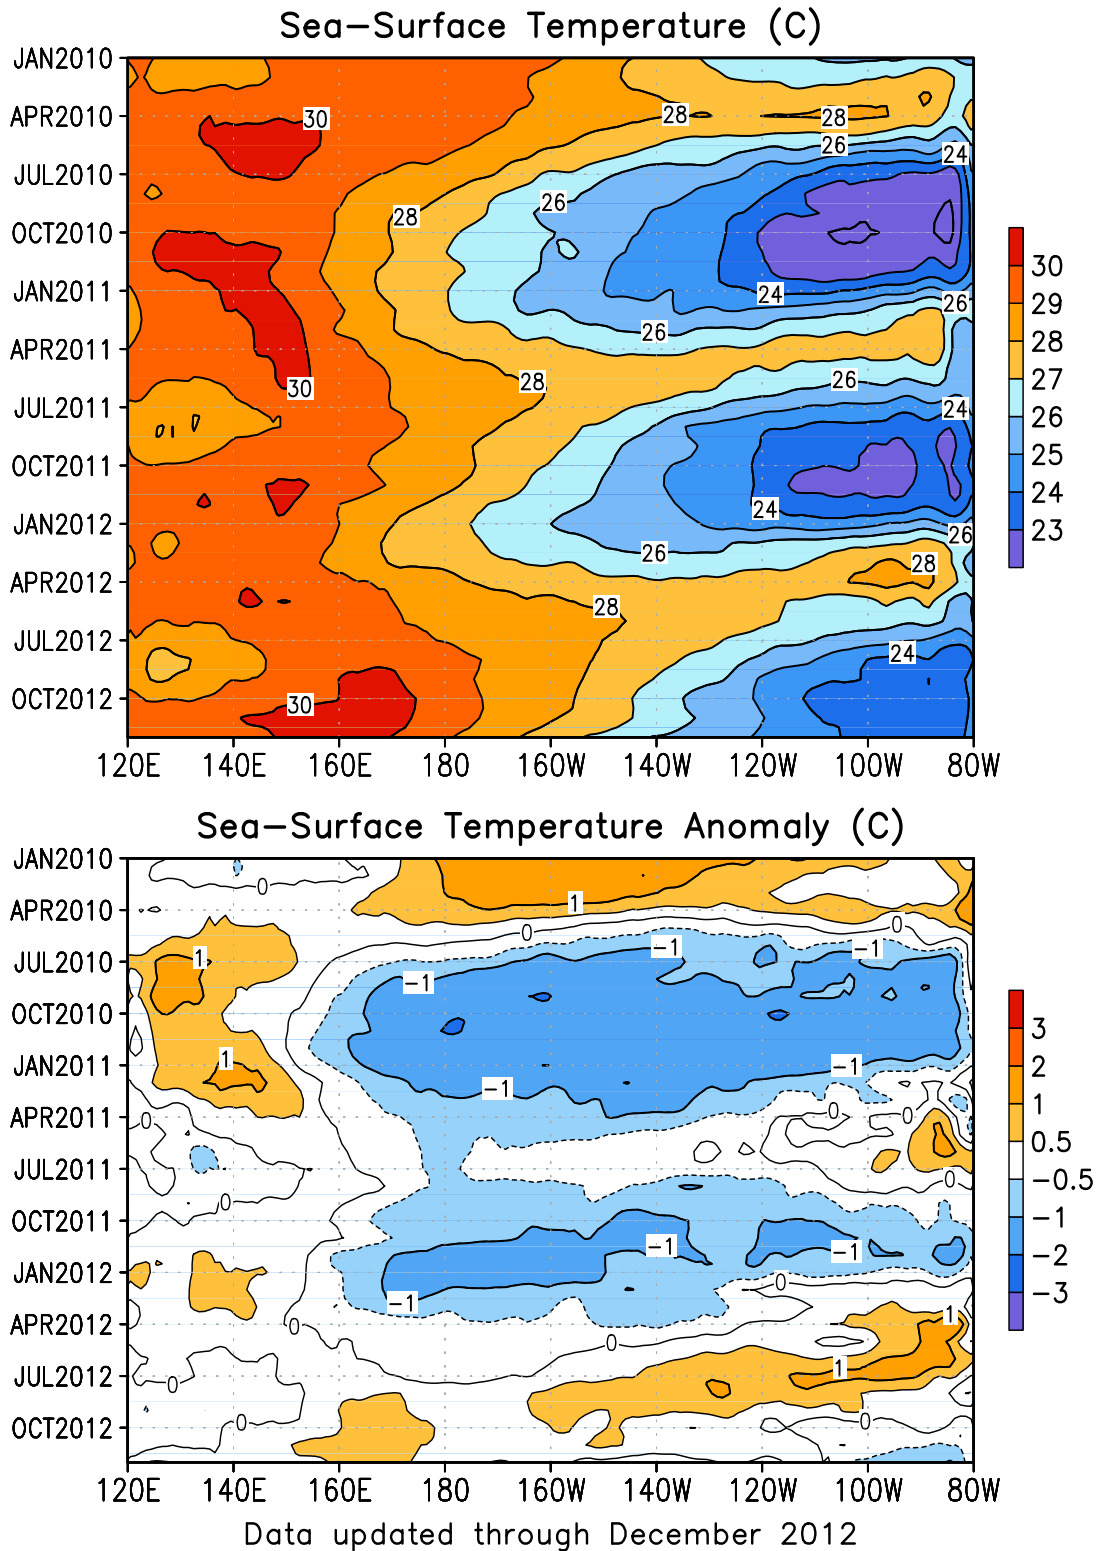

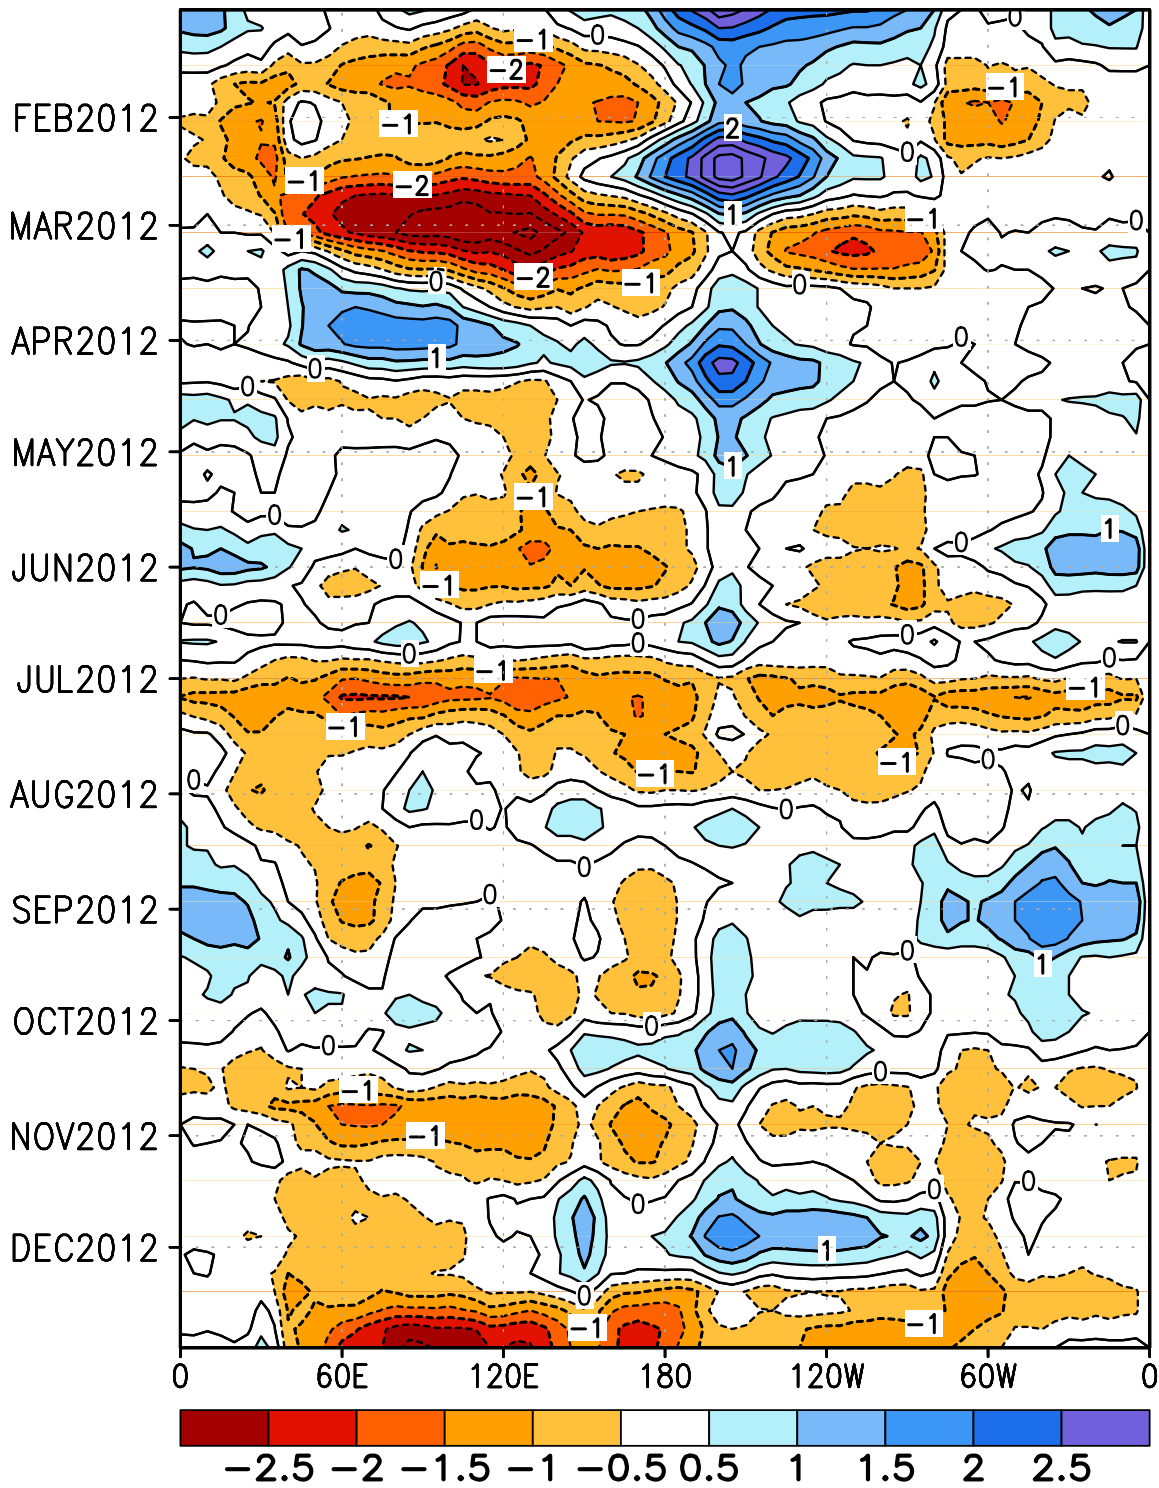

FIGURE T9. Time-longitude section of monthly mean (top) and anomalous (bottom) sea surface temperature (SST) averaged between 5N-5S. Contour interval is 1C (top) and 0.5C (bottom). Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1981-2010 base period means (Smith and Reynolds 1998, *J. Climate*, **11**, 3320-3323).

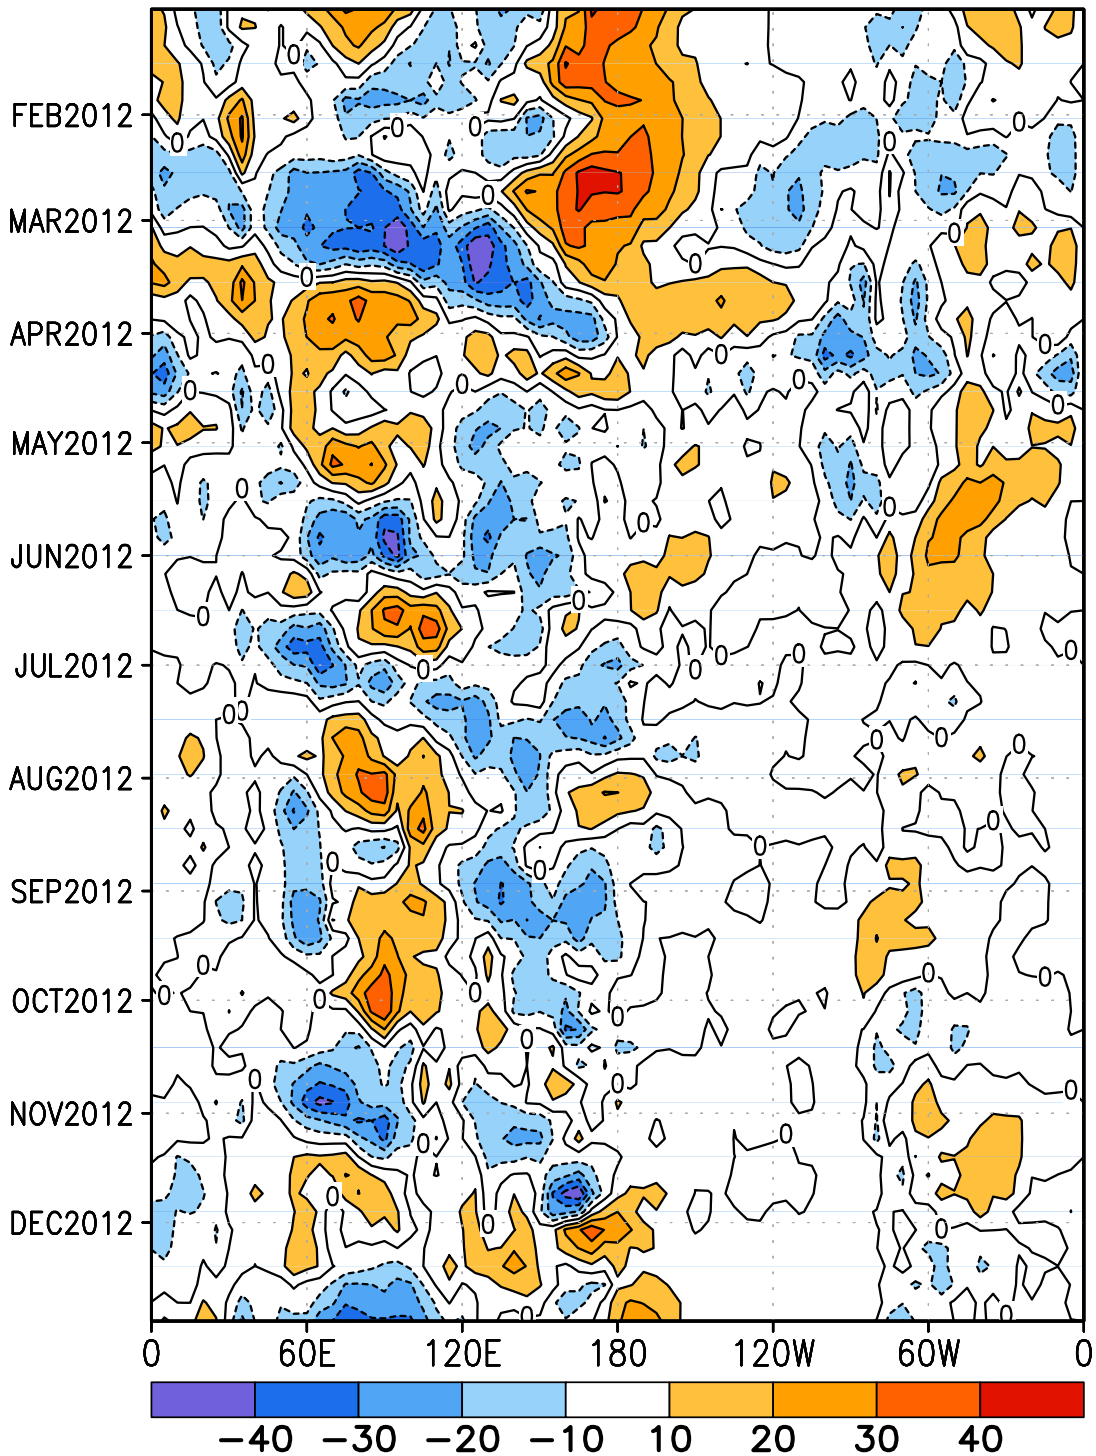

### Sea Level Pressure Anomaly (hPa)

Data updated through December 2012

FIGURE T10. Time-longitude section of anomalous sea level pressure (hPa) averaged between 5N-5S (CDAS/Re-analysis). Contour interval is 1 hPa. Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally using a 3-point running average.

## Outgoing Longwave Radiation Anomaly ( $\text{W}/\text{m}^2$ )

Data updated through December 2012

FIGURE T11. Time-longitude section of anomalous outgoing longwave radiation averaged between 5N-5S. Contour interval is  $15 \text{ Wm}^{-2}$ . Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally using a 3-point running average.

### 200-hPa Velocity Potential Anomaly

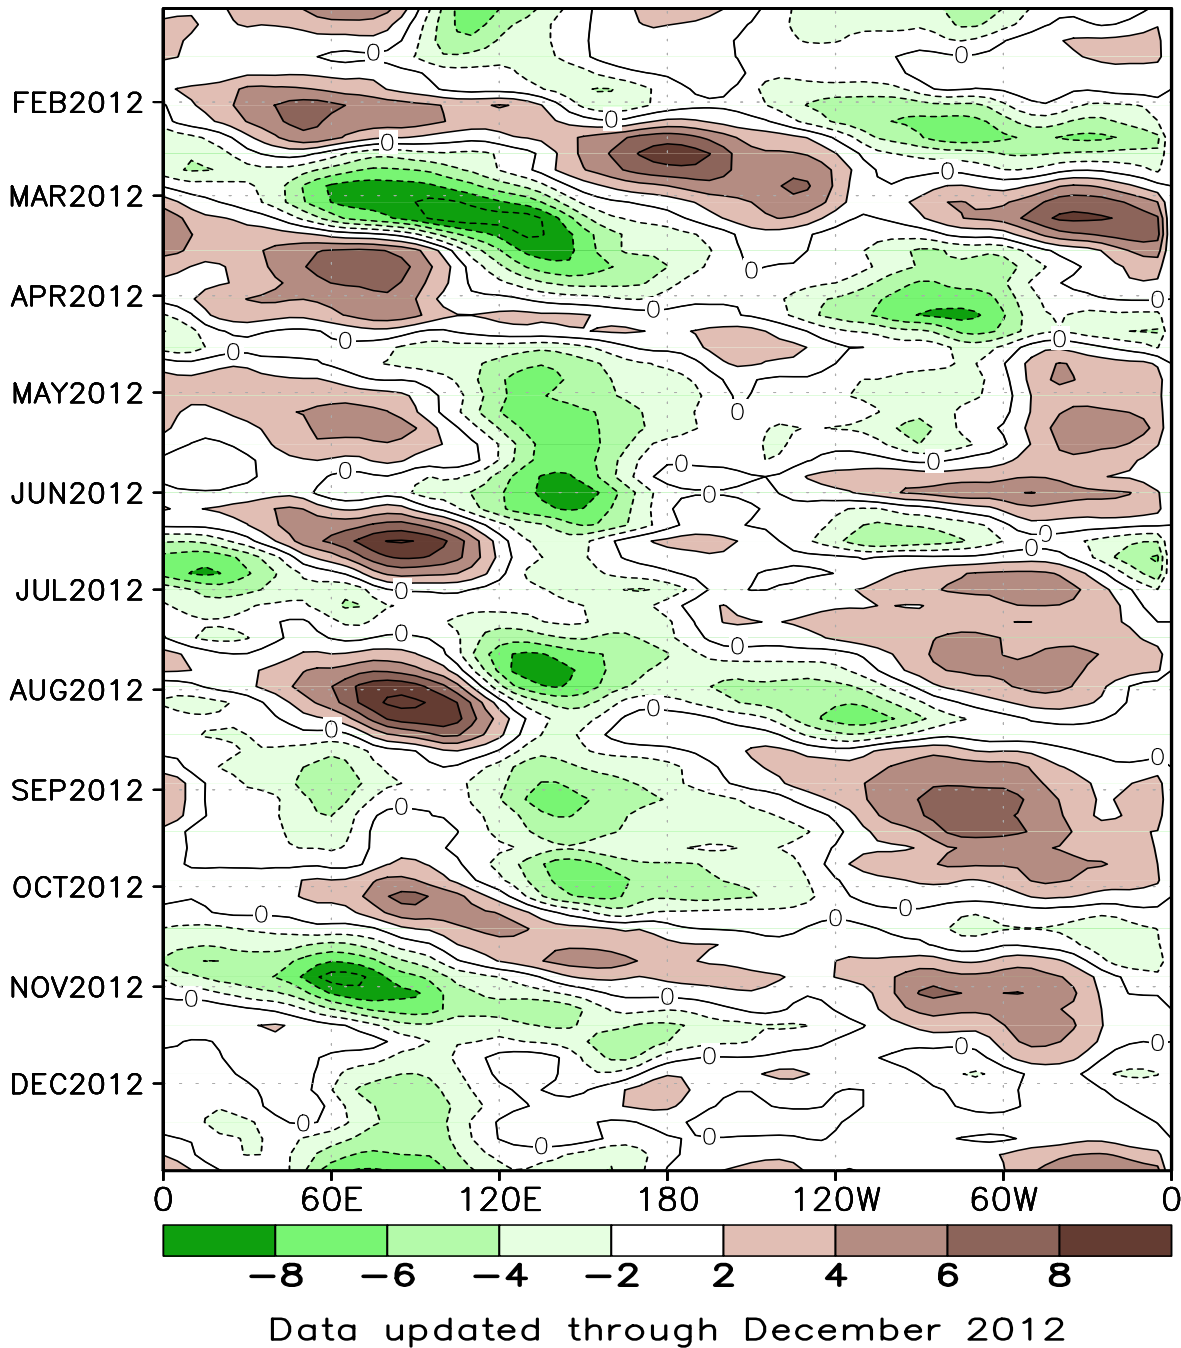

FIGURE T12. Time-longitude section of anomalous 200-hPa velocity potential averaged between 5N-5S (CDAS/Re-analysis). Contour interval is  $3 \times 10^6 \text{ m}^2 \text{ s}^{-1}$ . Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally using a 3-point running average.

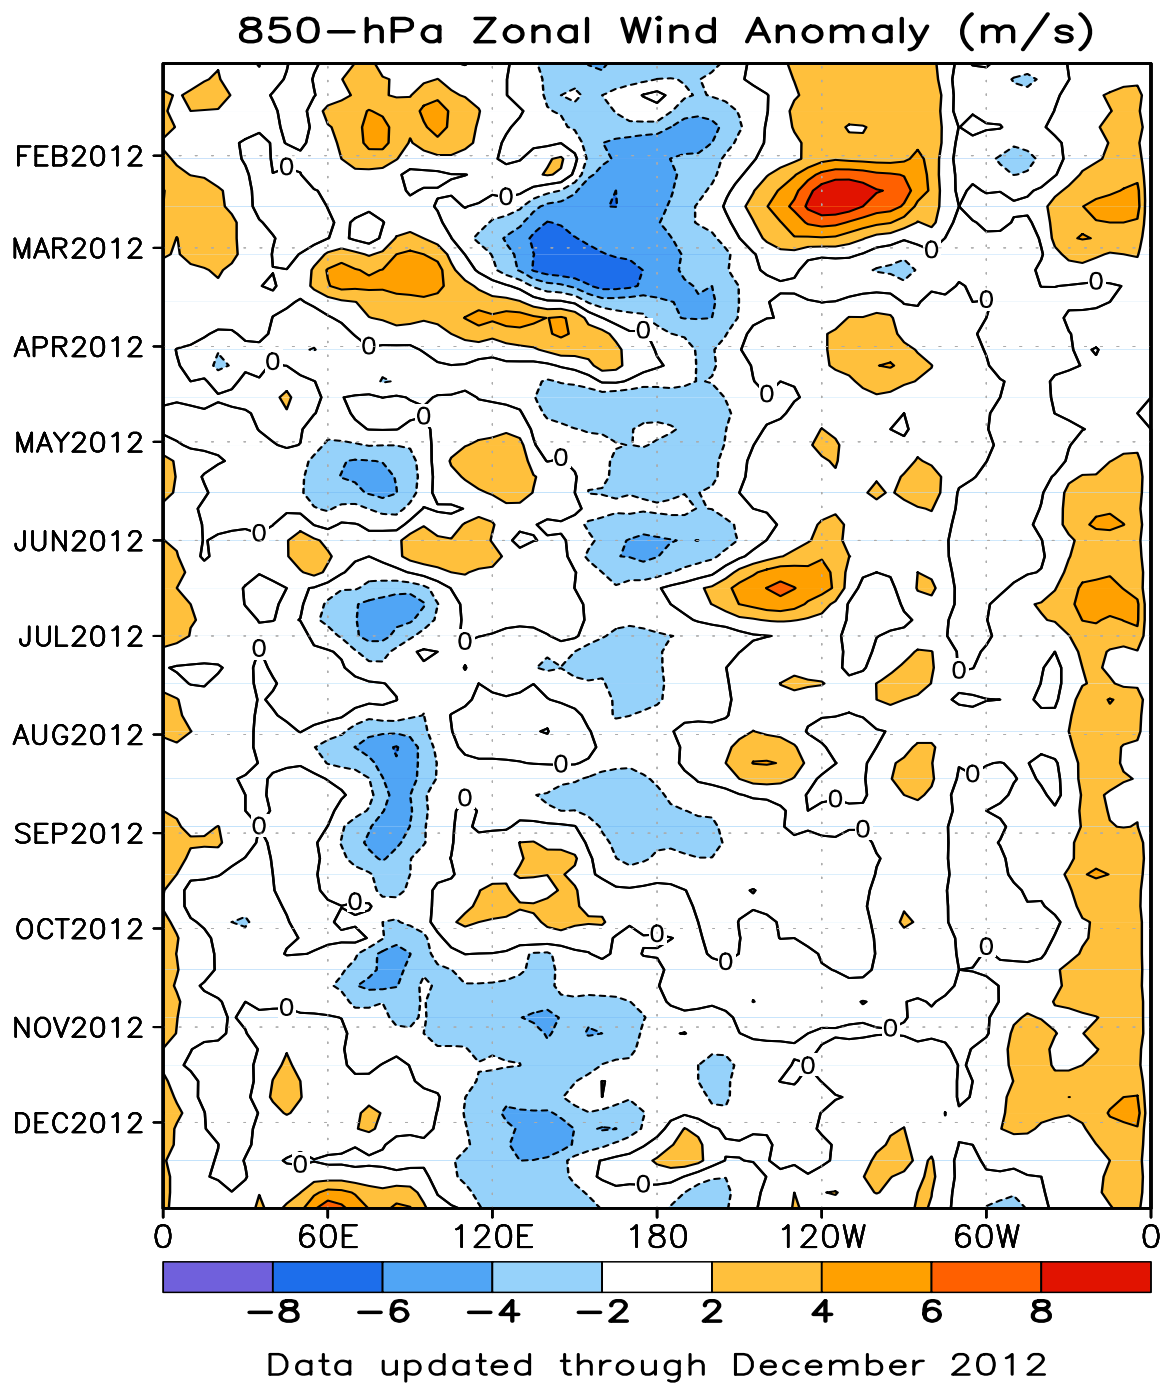

FIGURE T13. Time-longitude section of anomalous 850-hPa zonal wind averaged between 5N-5S (CDAS/Reanalysis). Contour interval is  $2 \text{ ms}^{-1}$ . Dashed contours indicate negative anomalies. Anomalies are departures from the 1981-2010 base period pentad means. The data are smoothed temporally by using a 3-point running average.

FIGURE T14. Equatorial time-height section of anomalous zonally-averaged zonal wind ( $\text{m s}^{-1}$ ) (CDAS/Reanalysis). Contour interval is  $10 \text{ m s}^{-1}$ . Anomalies are departures from the 1981-2010 base period monthly means.

FIGURE T15. Mean (top) and anomalous (bottom) depth of the 20C isotherm averaged between 5N-5S in the Pacific Ocean. Data are derived from the NCEP's global ocean data assimilation system which assimilates oceanic observations into an oceanic GCM (Behringer, D. W., and Y. Xue, 2004: Evaluation of the global ocean data assimilation system at NCEP: The Pacific Ocean. AMS 84th Annual Meeting, Seattle, Washington, 11-15). The contour interval is 10 m. Dashed contours in bottom panel indicate negative anomalies. Anomalies are departures from the 1981-2010 base period means.

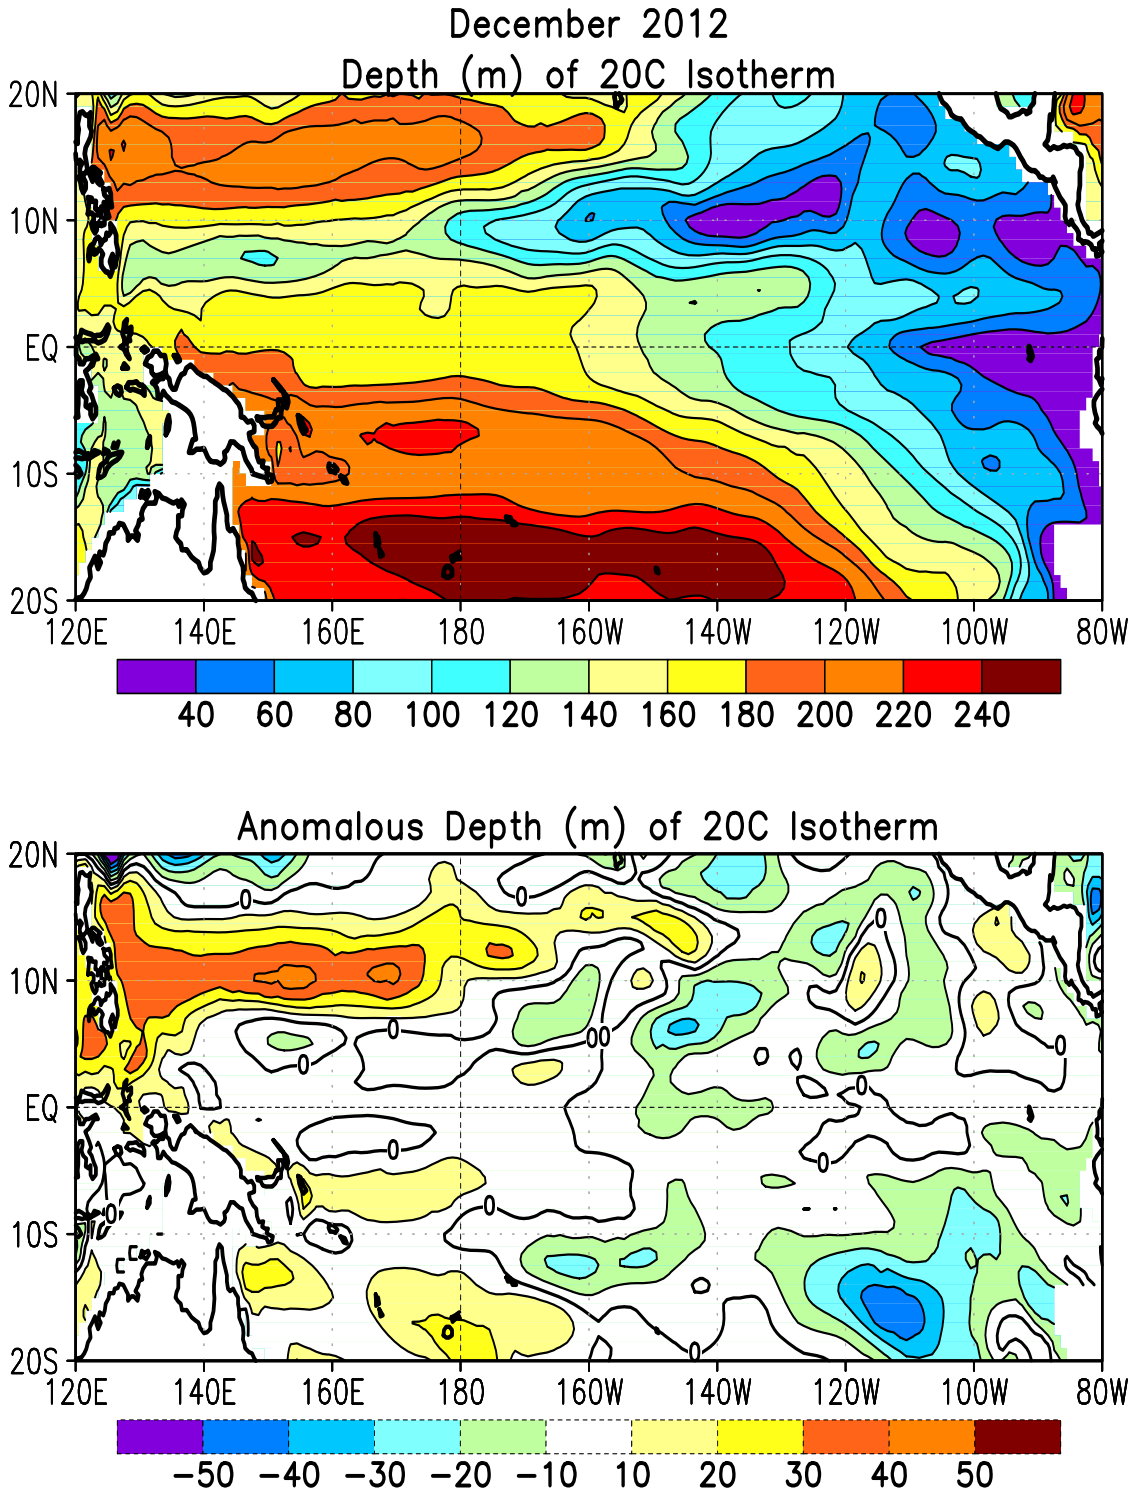

FIGURE T16. Mean (top) and anomalous (bottom) depth of the 20°C isotherm for DEC 2012. Contour interval is 40 m (top) and 10 m (bottom). Dashed contours in bottom panel indicate negative anomalies. Data are derived from the NCEP's global ocean data assimilation system version 2 which assimilates oceanic observations into an oceanic GCM (Xue, Y. and Behringer, D.W., 2006: Operational global ocean data assimilation system at NCEP, to be submitted to BAMS). Anomalies are departures from the 1981–2010 base period means.

December 2012: Depth–Longitude Section  
Equatorial Ocean Temperatures (C)

Equatorial Ocean Temperature Anomalies (C)

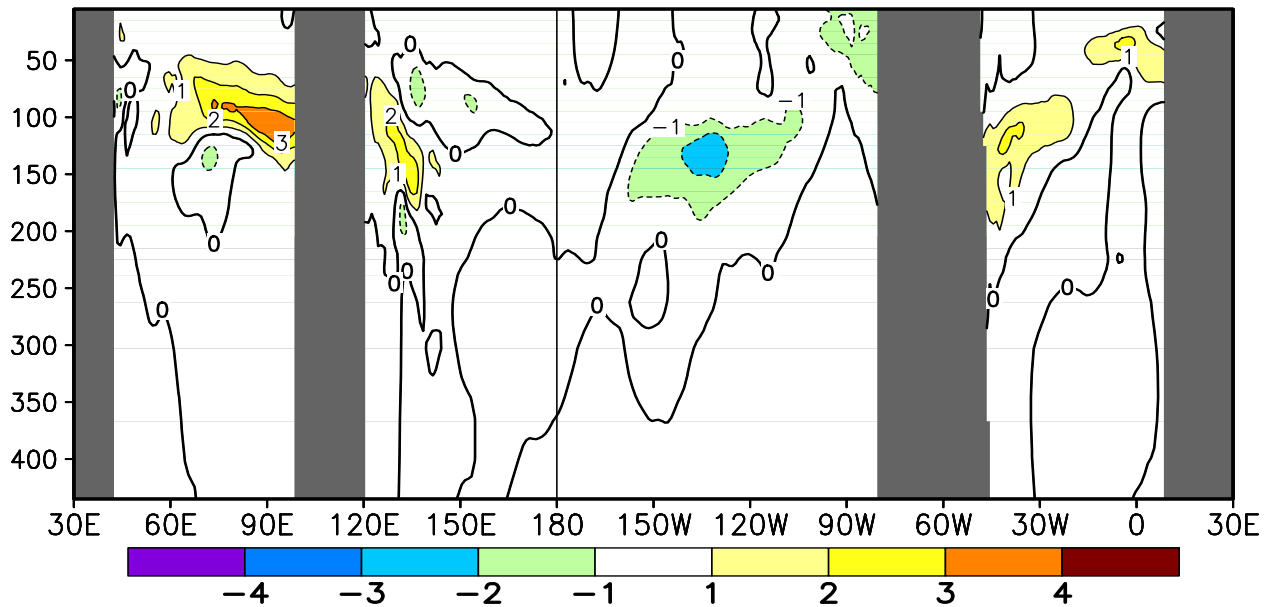

FIGURE T17. Equatorial depth–longitude section of ocean temperature (top) and ocean temperature anomalies (bottom) for DEC 2012. Contour interval is 1°C. Dashed contours in bottom panel indicate negative anomalies. Data are derived from the NCEP’s global ocean data assimilation system version 2 which assimilates oceanic observations into an oceanic GCM (Xue, Y. and Behringer, D.W., 2006: Operational global ocean data assimilation system at NCEP, to be submitted to BAMS). Anomalies are departures from the 1981–2010 base period means.

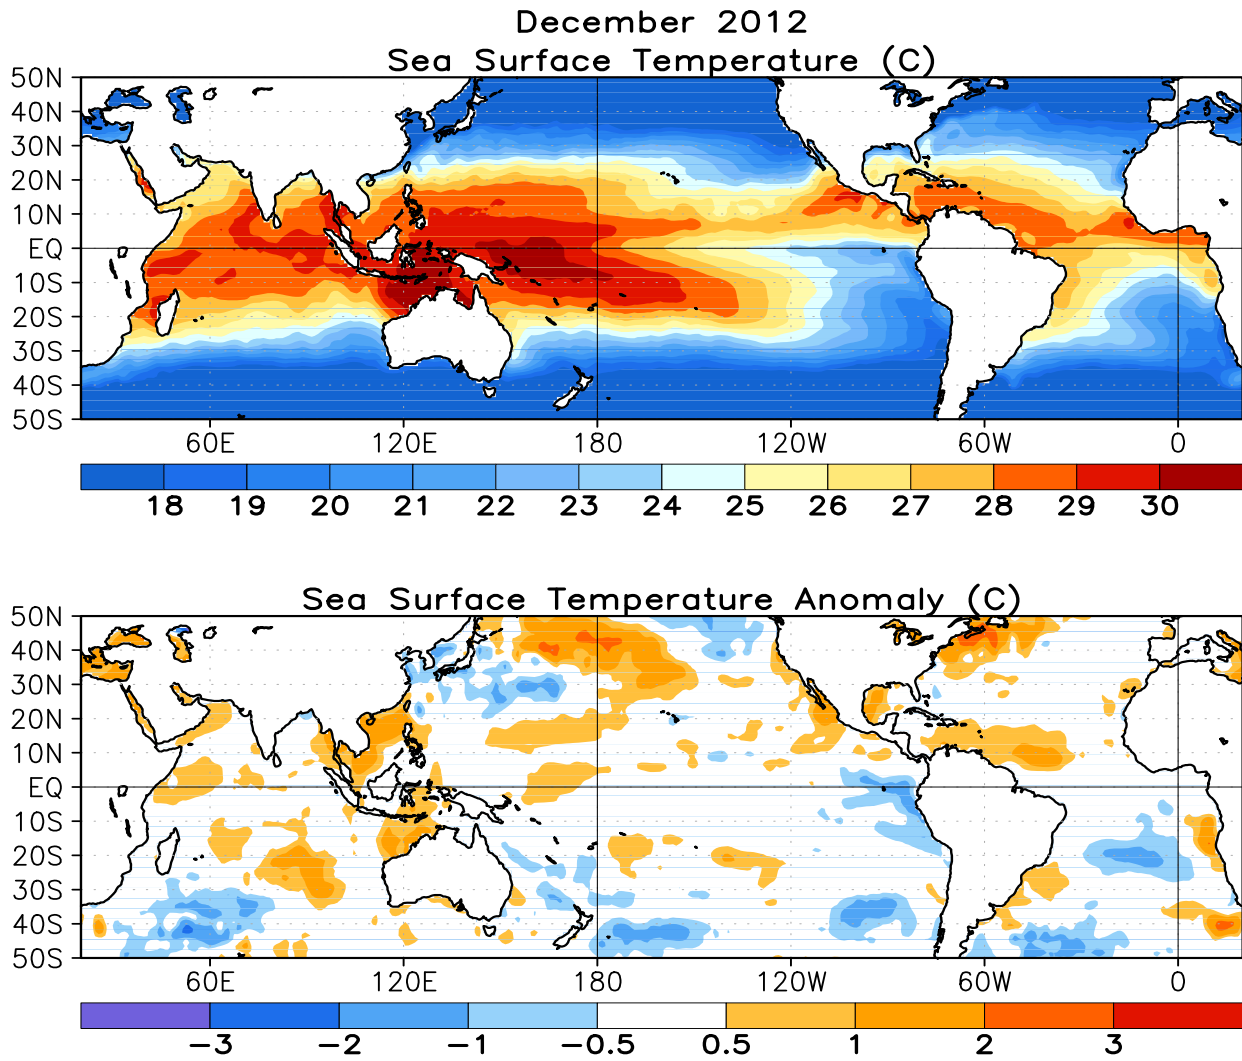

FIGURE T18. Mean (top) and anomalous (bottom) sea surface temperature (SST). Anomalies are departures from the 1981-2010 base period monthly means (Smith and Reynolds 1998, *J. Climate*, **11**, 3320-3323).

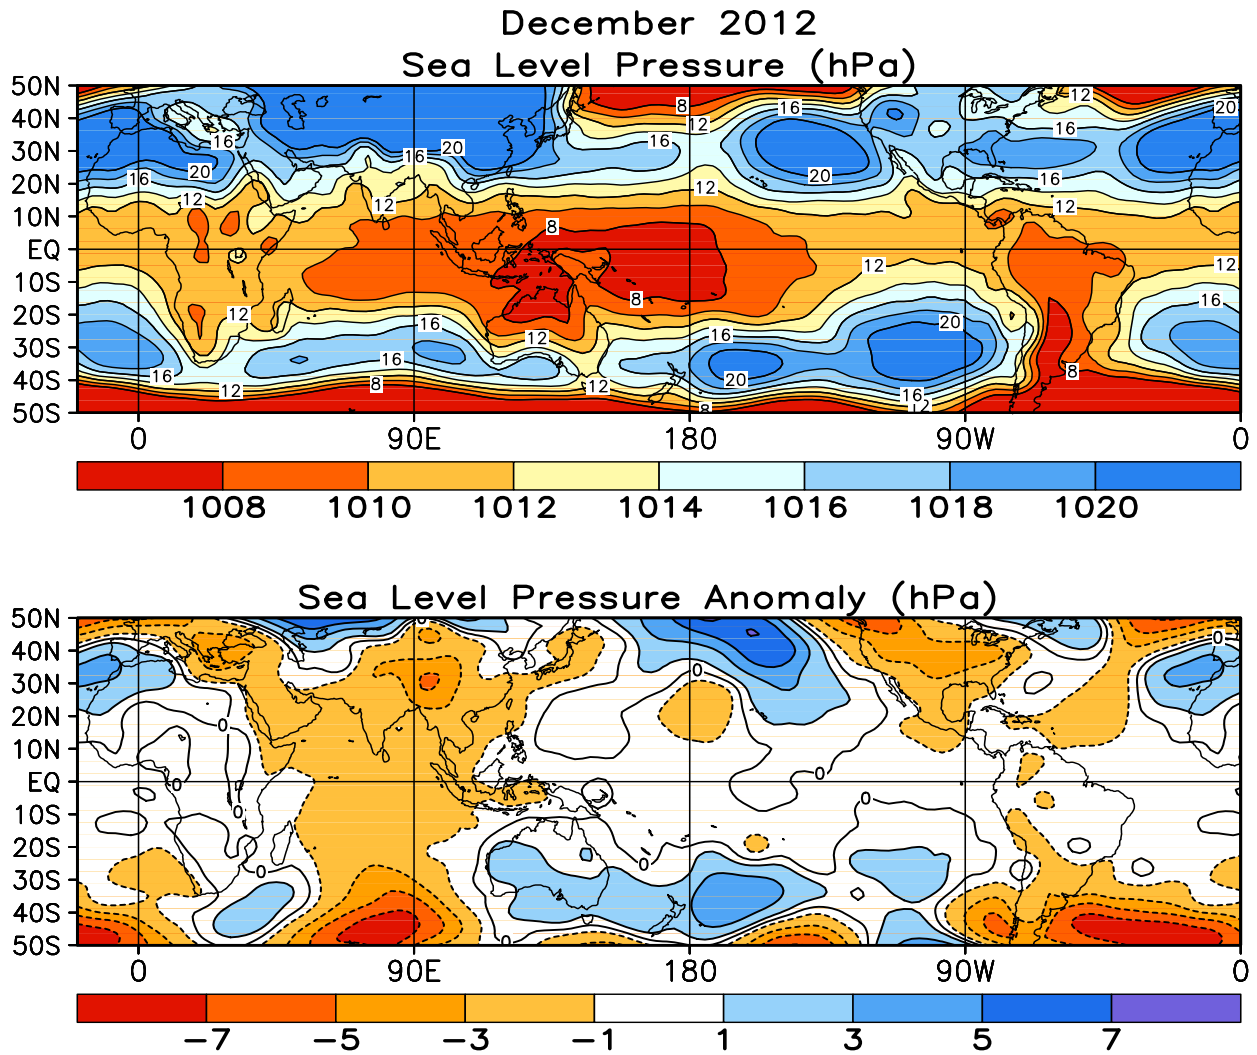

FIGURE T19. Mean (top) and anomalous (bottom) sea level pressure (SLP) (CDAS/Reanalysis). In top panel, 1000 hPa has been subtracted from contour labels, contour interval is 2 hPa, and values below 1000 hPa are indicated by dashed contours. In bottom panel, anomaly contour interval is 1 hPa and negative anomalies are indicated by dashed contours. Anomalies are departures from the 1981-2010 base period monthly means.

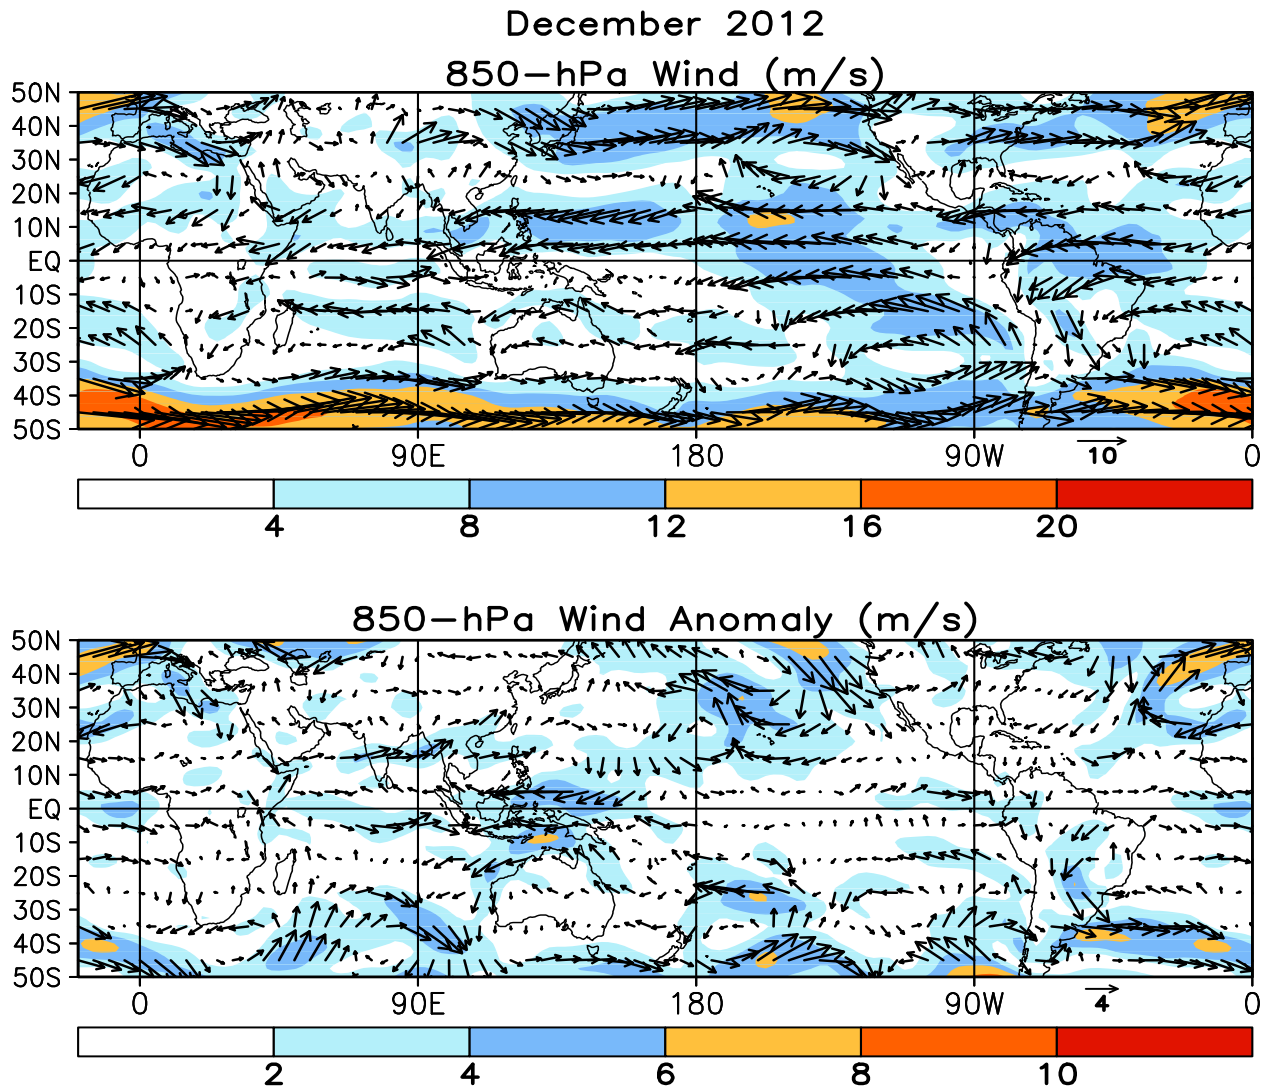

FIGURE T20. Mean (top) and anomalous (bottom) 850-hPa vector wind (CDAS/Reanalysis) for DEC 2012. Contour interval for isotachs is  $4 \text{ ms}^{-1}$  (top) and  $2 \text{ ms}^{-1}$  (bottom). Anomalies are departures from the 1981-2010 base period monthly means.

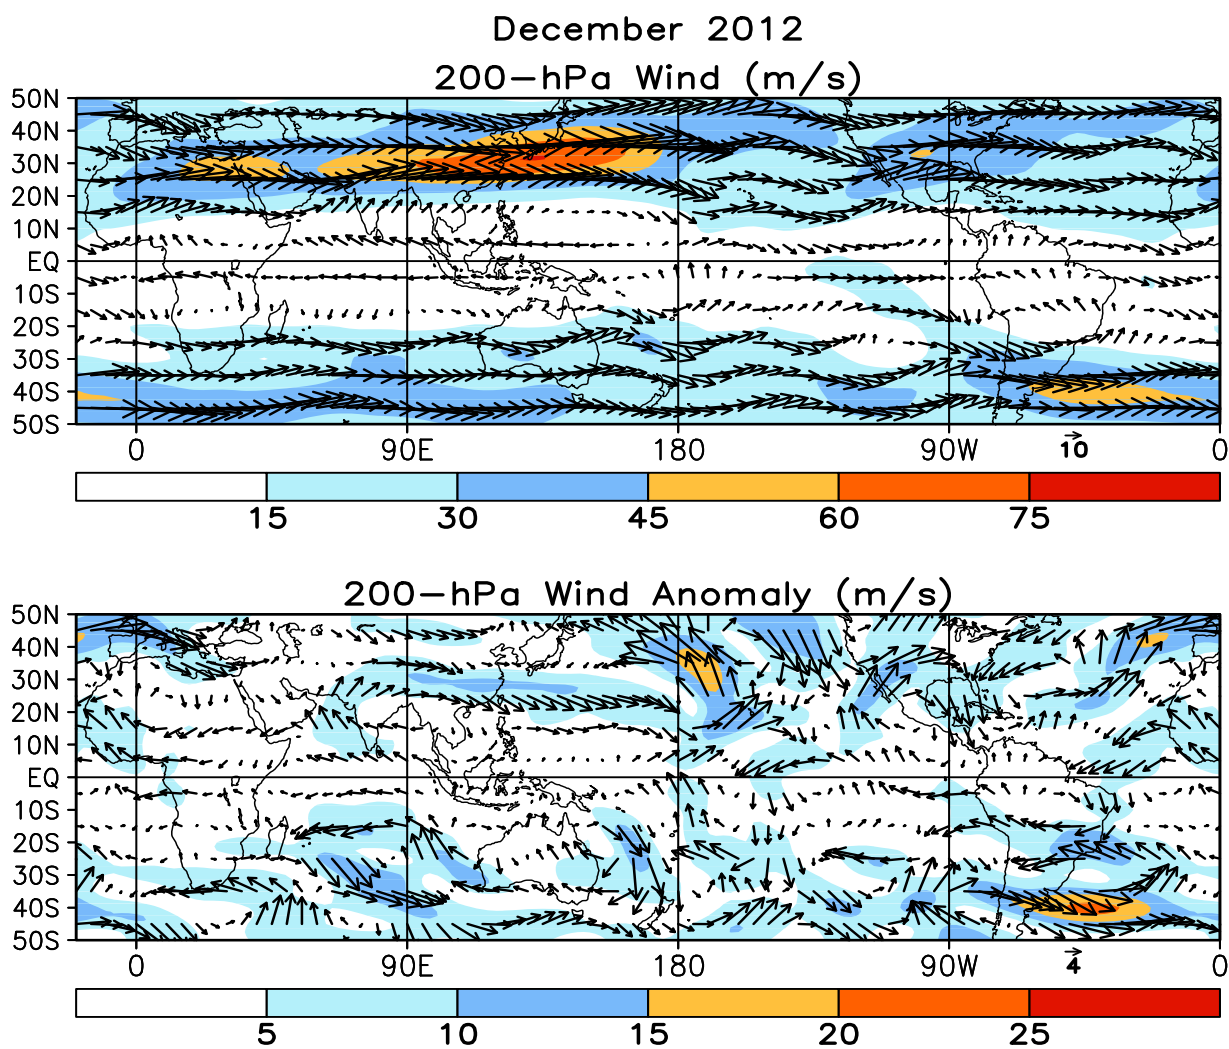

FIGURE T21. Mean (top) and anomalous (bottom) 200-hPa vector wind (CDAS/Reanalysis) for DEC 2012. Contour interval for isotachs is  $15 \text{ ms}^{-1}$  (top) and  $5 \text{ ms}^{-1}$  (bottom). Anomalies are departures from 1981-2010 base period monthly means.

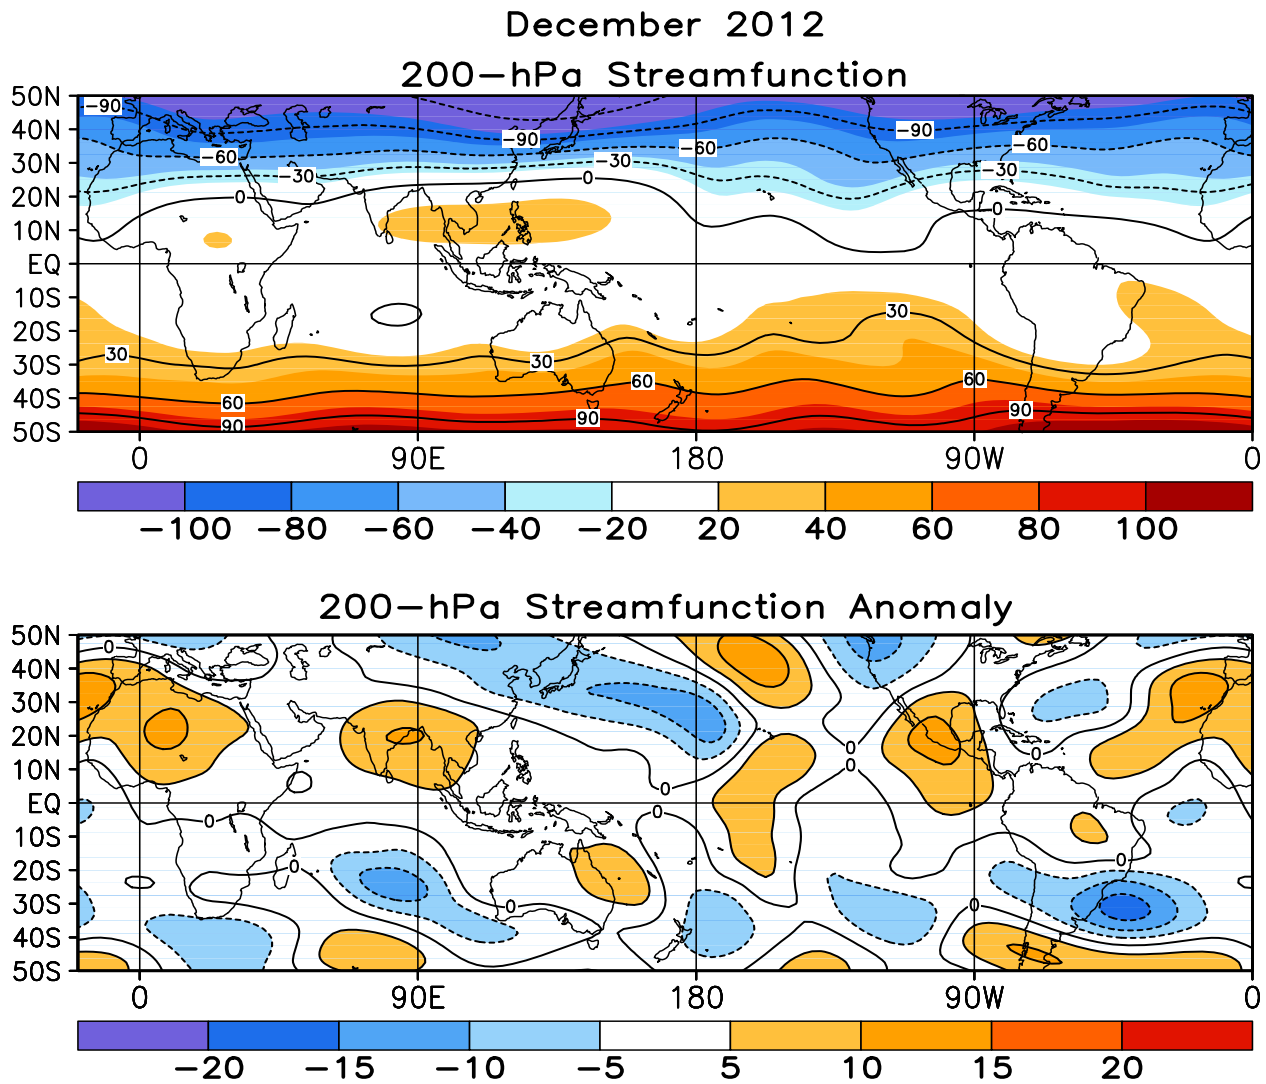

FIGURE T22. Mean (top) and anomalous (bottom) 200-hPa streamfunction (CDAS/Reanalysis). Contour interval is  $20 \times 10^6 \text{ m}^2\text{s}^{-1}$  (top) and  $5 \times 10^6 \text{ m}^2\text{s}^{-1}$  (bottom). Negative (positive) values are indicated by dashed (solid) lines. The non-divergent component of the flow is directed along the contours with speed proportional to the gradient. Thus, high (low) stream function corresponds to high (low) geopotential height in the Northern Hemisphere and to low (high) geopotential height in the Southern Hemisphere. Anomalies are departures from the 1981-2010 base period monthly means.

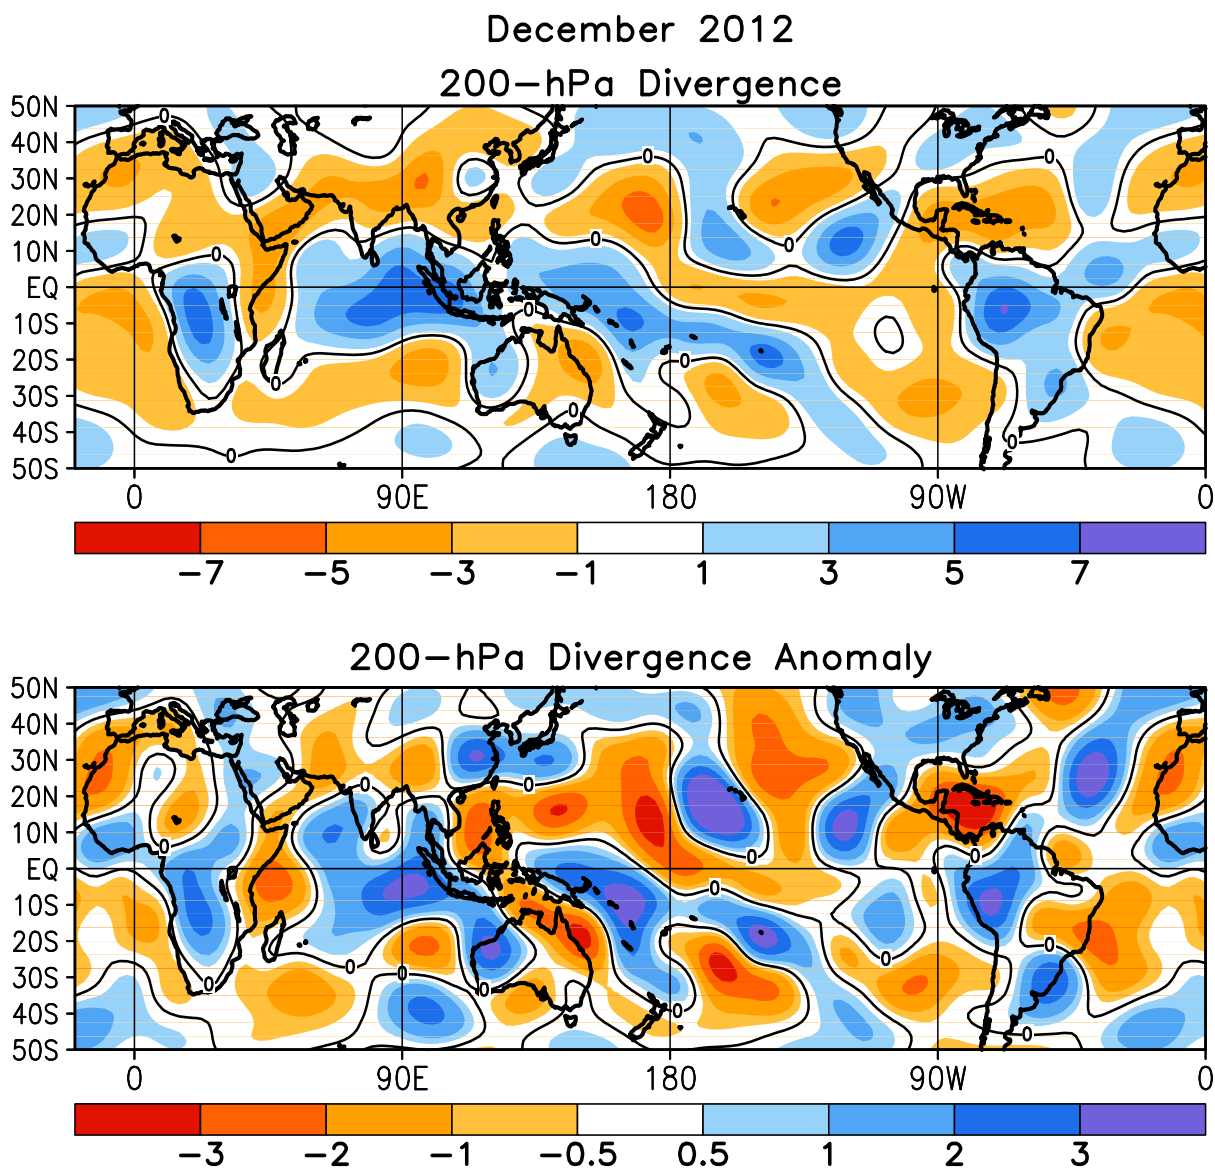

FIGURE T23. Mean (top) and anomalous (bottom) 200-hPa divergence (CDAS/Reanalysis). Divergence and anomalous divergence are shaded blue. Convergence and anomalous convergence are shaded orange. Anomalies are departures from the 1981-2010 base period monthly means.

December 2012

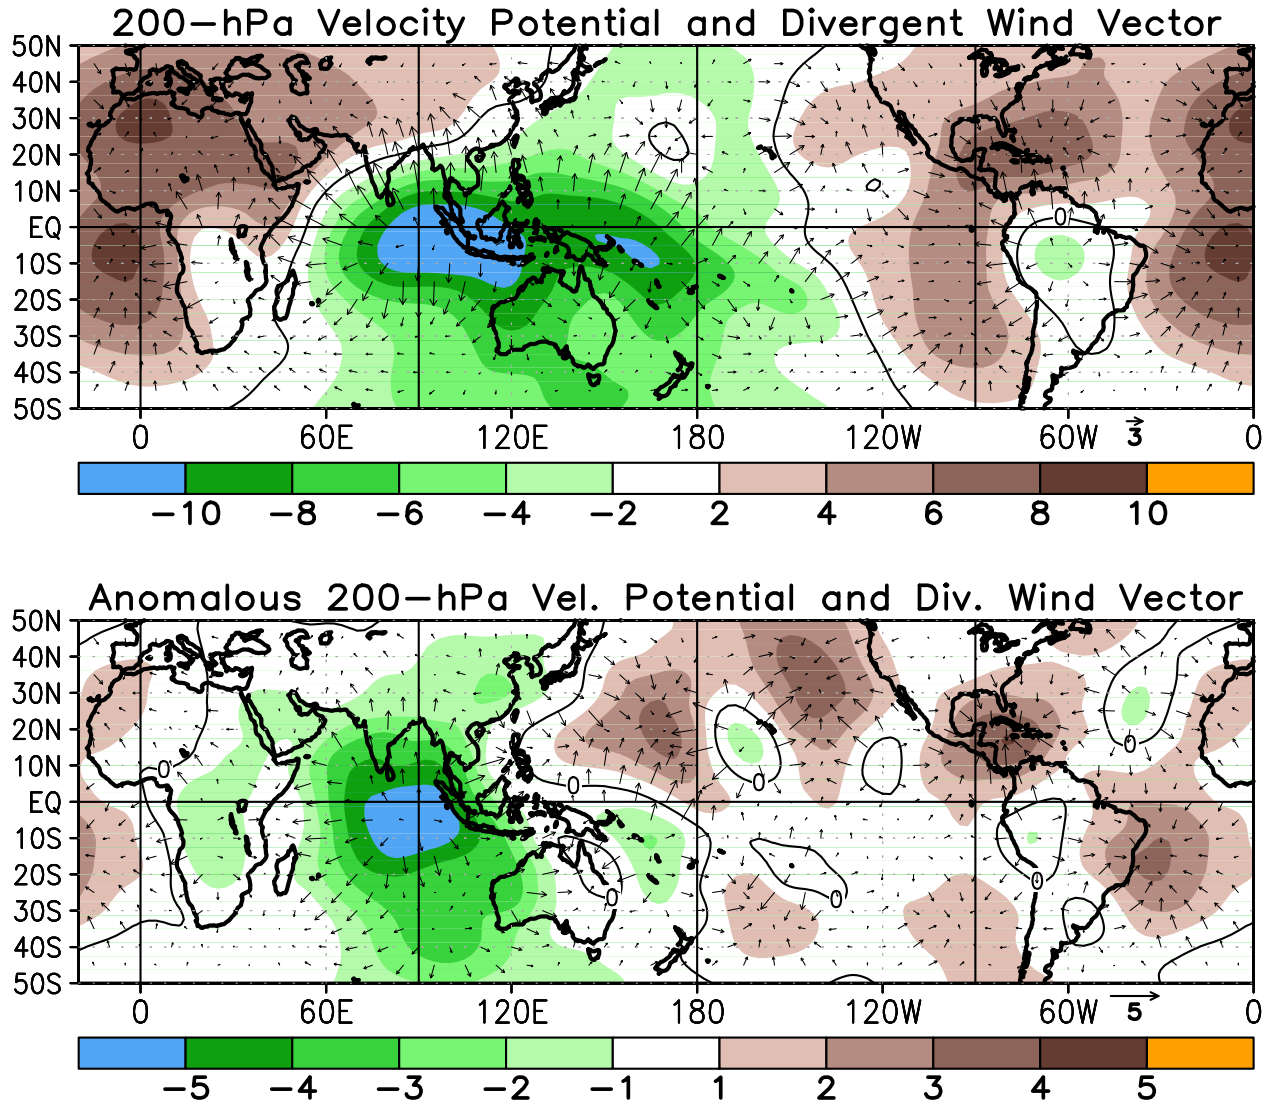

FIGURE T24. Mean (top) and anomalous (bottom) 200-hPa velocity potential ( $10^6\text{m}^2\text{s}$ ) and divergent wind (CDAS/Reanalysis). Anomalies are departures from the 1981-2010 base period monthly means.

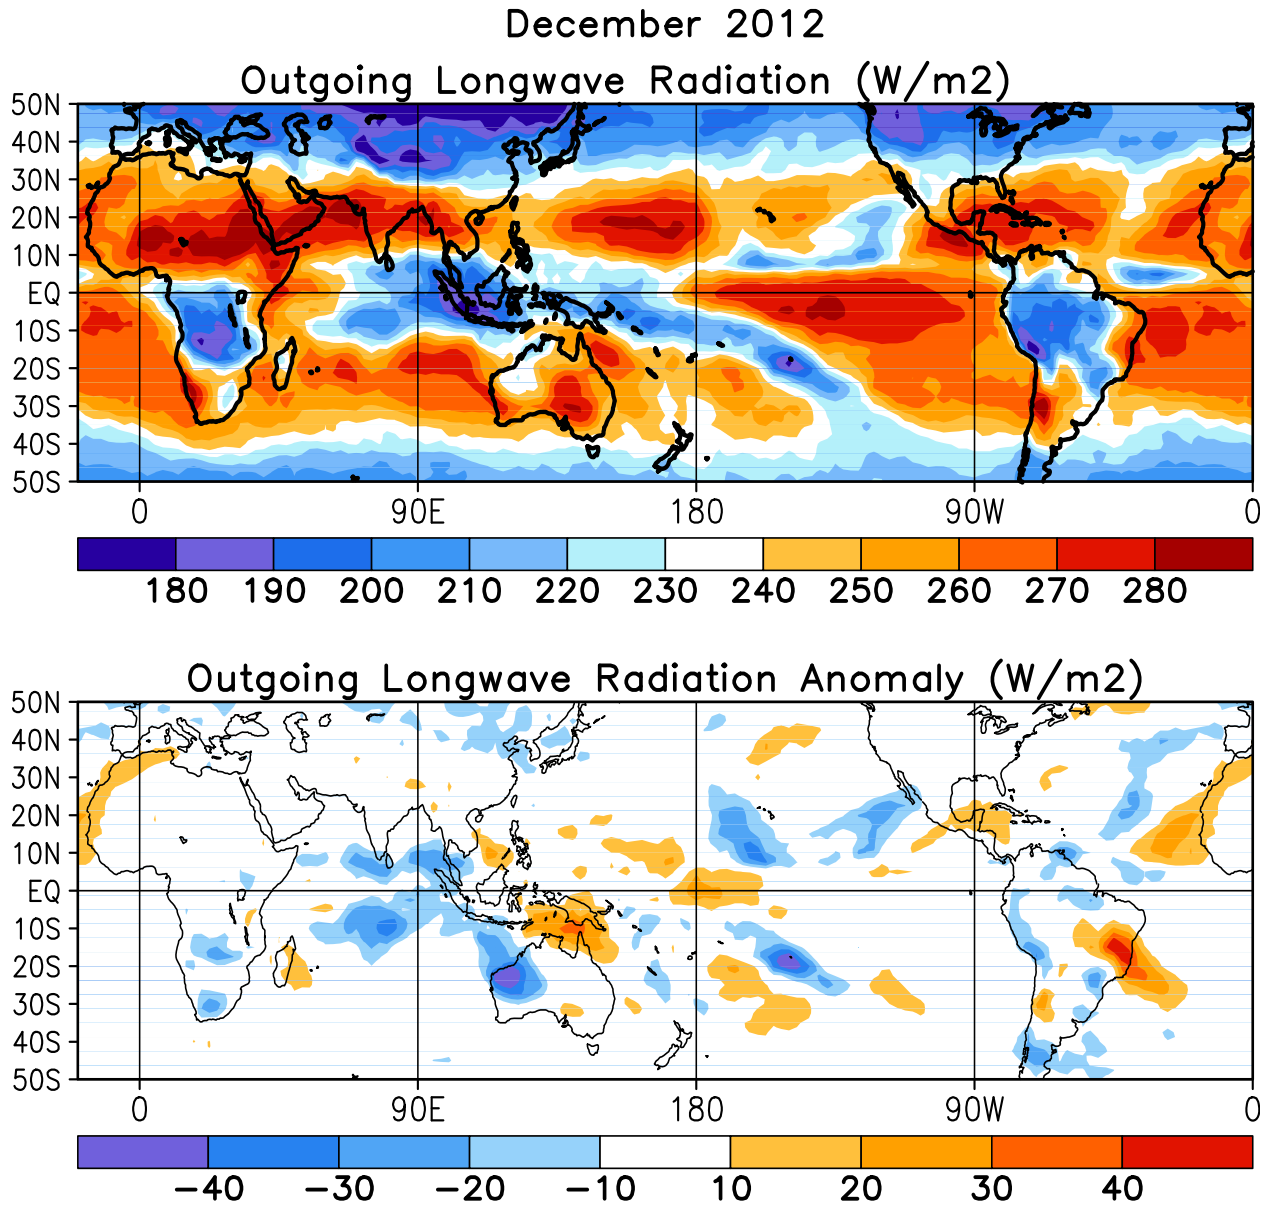

FIGURE T25. Mean (top) and anomalous (bottom) outgoing longwave radiation for DEC 2012 (NOAA 18 AVHRR IR window channel measurements by NESDIS/ORR). OLR contour interval is 20 Wm<sup>-2</sup> with values greater than 280 Wm<sup>-2</sup> indicated by dashed contours. Anomaly contour interval is 15 Wm<sup>-2</sup> with positive values indicated by dashed contours and light shading. Anomalies are departures from the 1981-2010 base period monthly means.

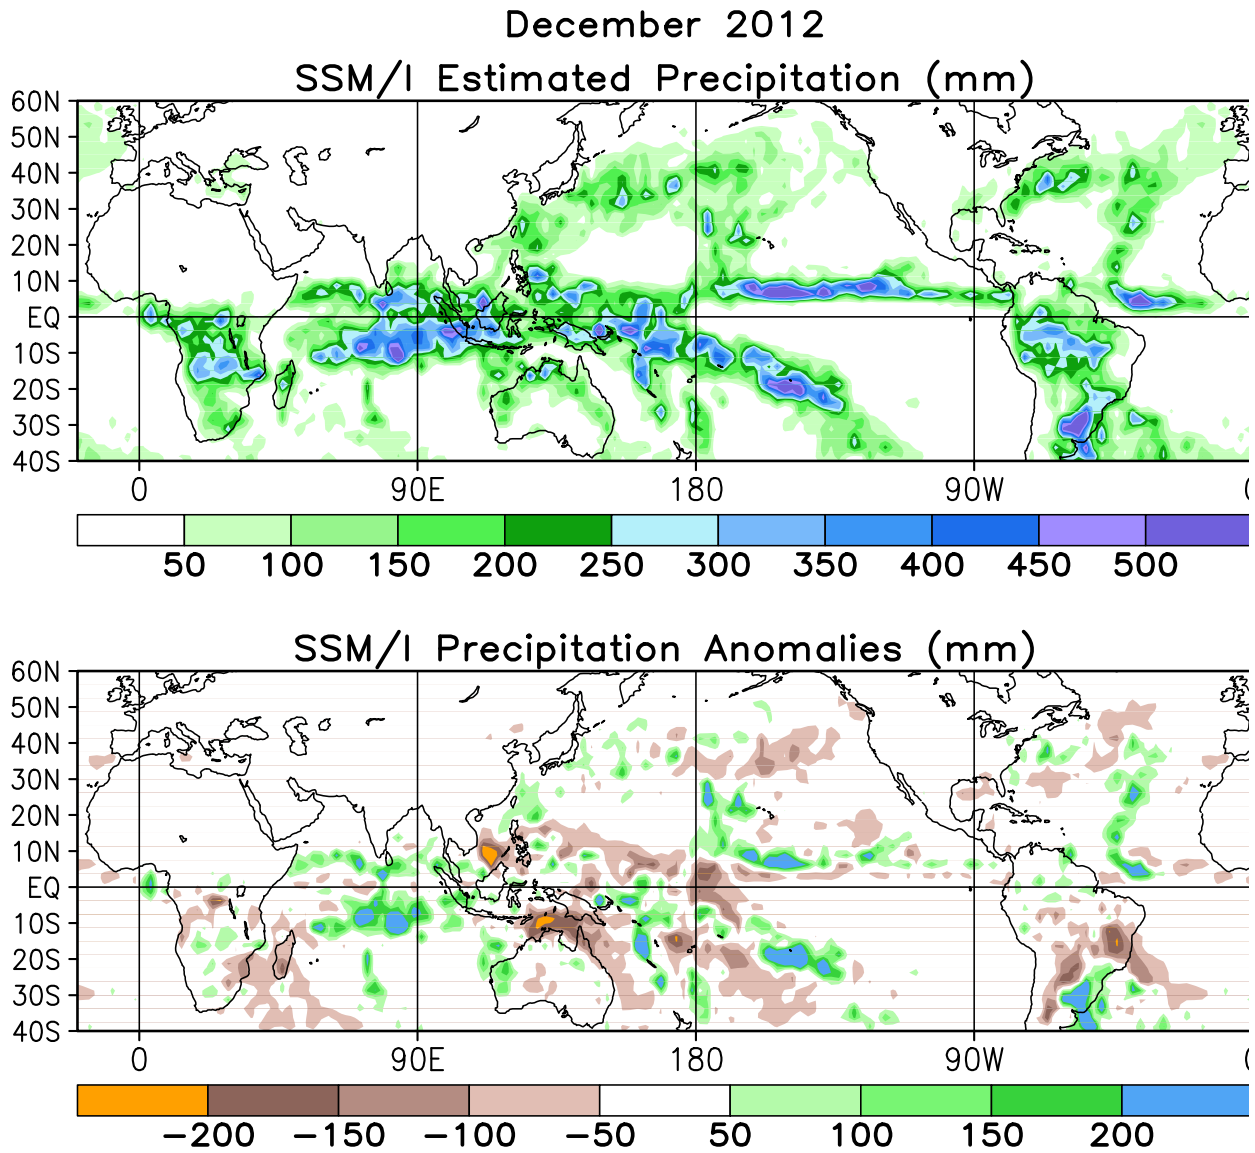

FIGURE T26. Estimated total (top) and anomalous (bottom) rainfall (mm) based on the Special Sensor Microwave/Imager (SSM/S) precipitation index (Ferraro 1997, *J. Geophys. Res.*, **102**, 16715-16735). Anomalies are computed from the SSM/I 1987-2010 base period monthly means. Anomalies have been smoothed for display purposes.

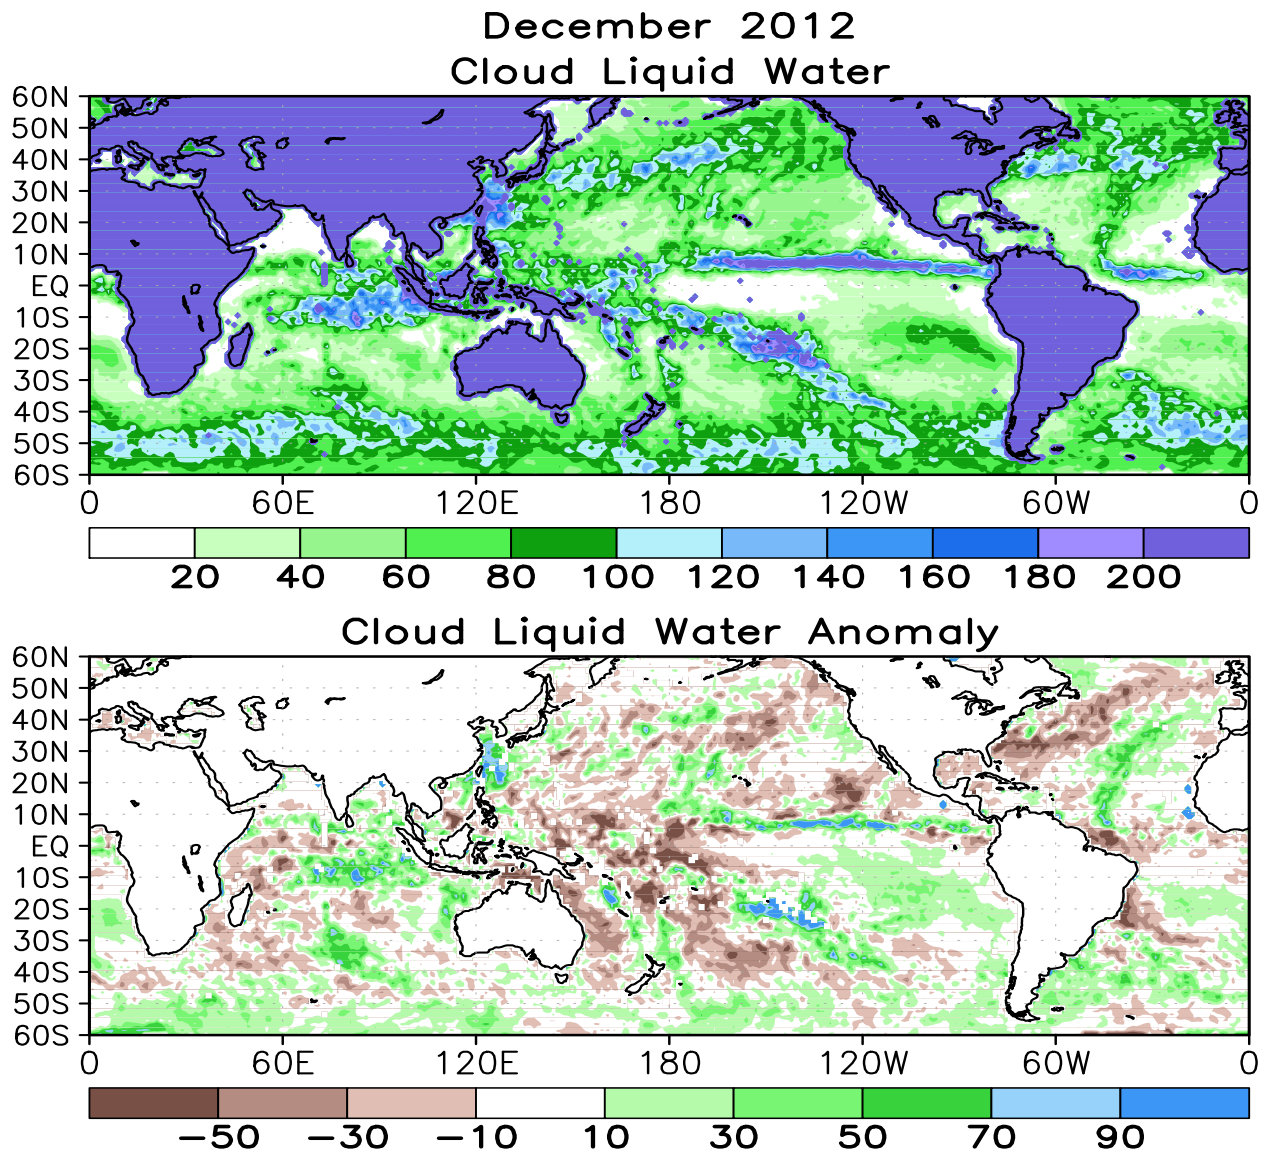

FIGURE T27. Mean (top) and anomalous (bottom) cloud liquid water ( $\text{g m}^{-2}$ ) based on the Special Sensor Microwave/Imager (SSM/I) (Weng et al 1997: *J. Climate*, **10**, 1086-1098). Anomalies are calculated from the 1987-2010 base period means.

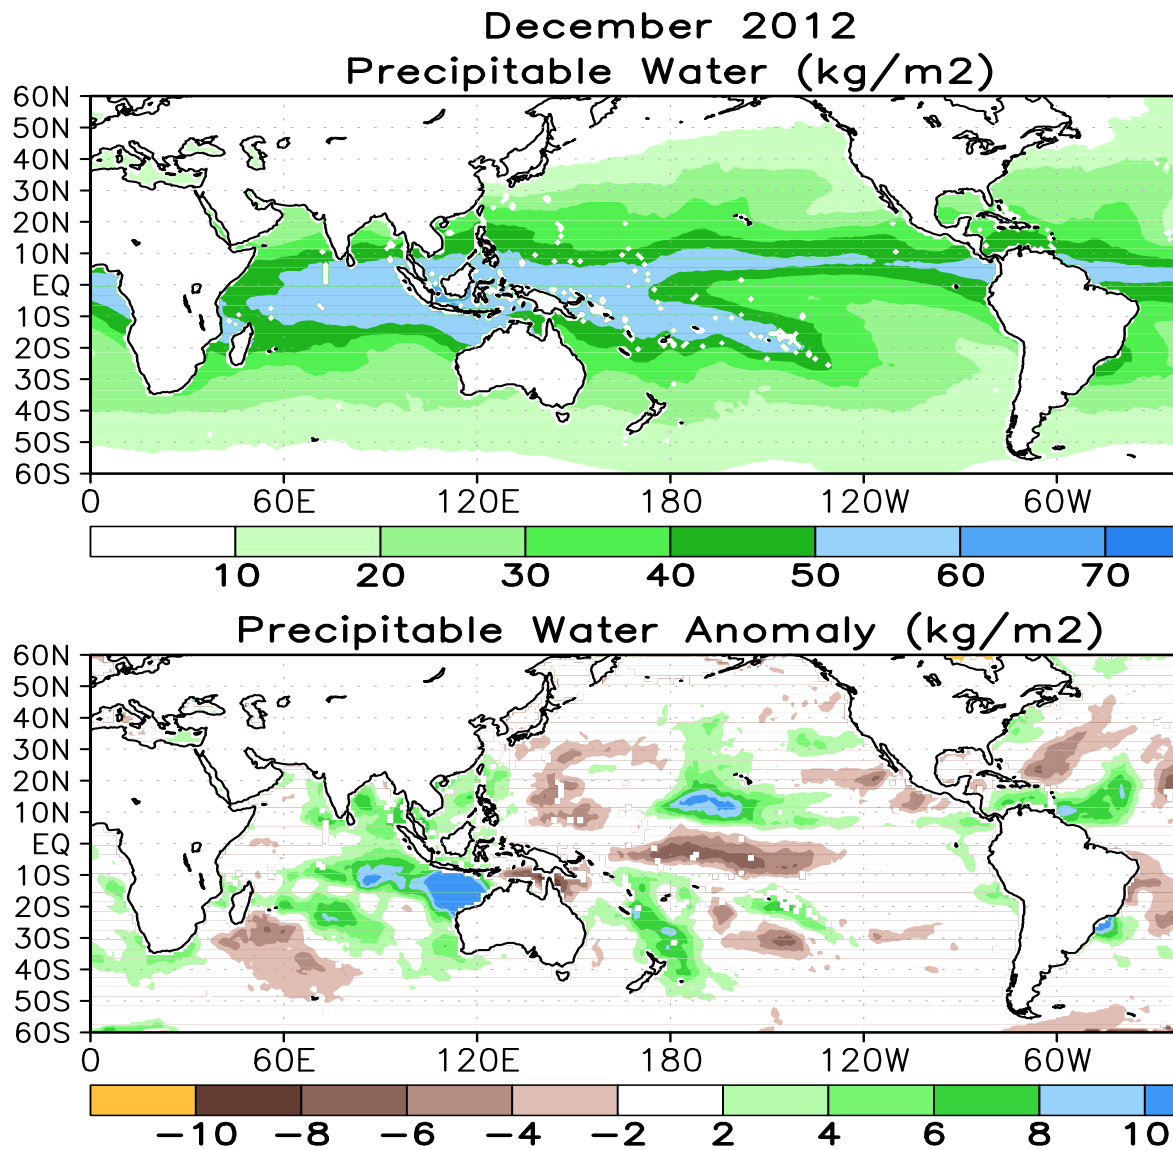

FIGURE T28. Mean (top) and anomalous (bottom) vertically integrated water vapor or precipitable water (kg m<sup>-2</sup>) based on the Special Sensor Microwave/Imager (SSM/I) (Ferraro et. al, 1996: *Bull. Amer. Meteor. Soc.*, **77**, 891-905). Anomalies are calculated from the 1987-2010 base period means.

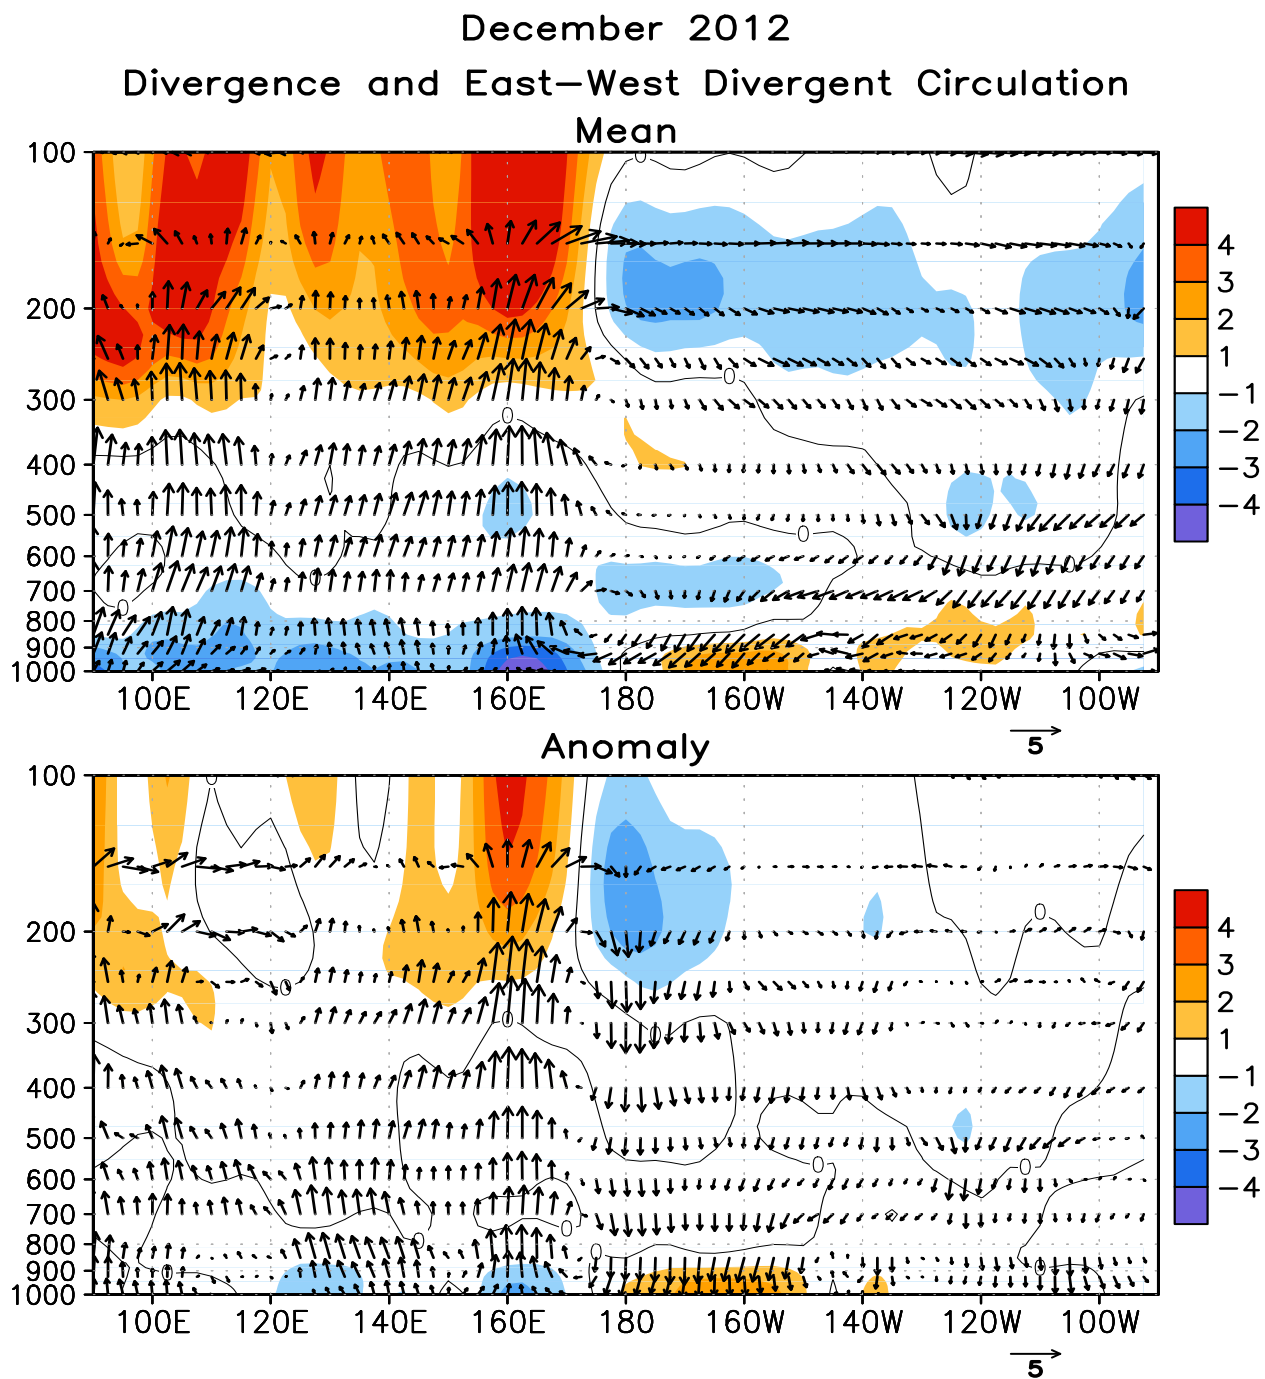

FIGURE T29. Pressure-longitude section (100E–80W) of the mean (top) and anomalous (bottom) divergence (contour interval is  $1 \times 10^{-6} \text{ s}^{-1}$ ) and divergent circulation averaged between 5N–5S. The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the zonal wind. Red shading and solid contours denote divergence (top) and anomalous divergence (bottom). Blue shading and dashed contours denote convergence (top) and anomalous convergence (bottom). Anomalies are departures from the 1981–2010 base period monthly means.

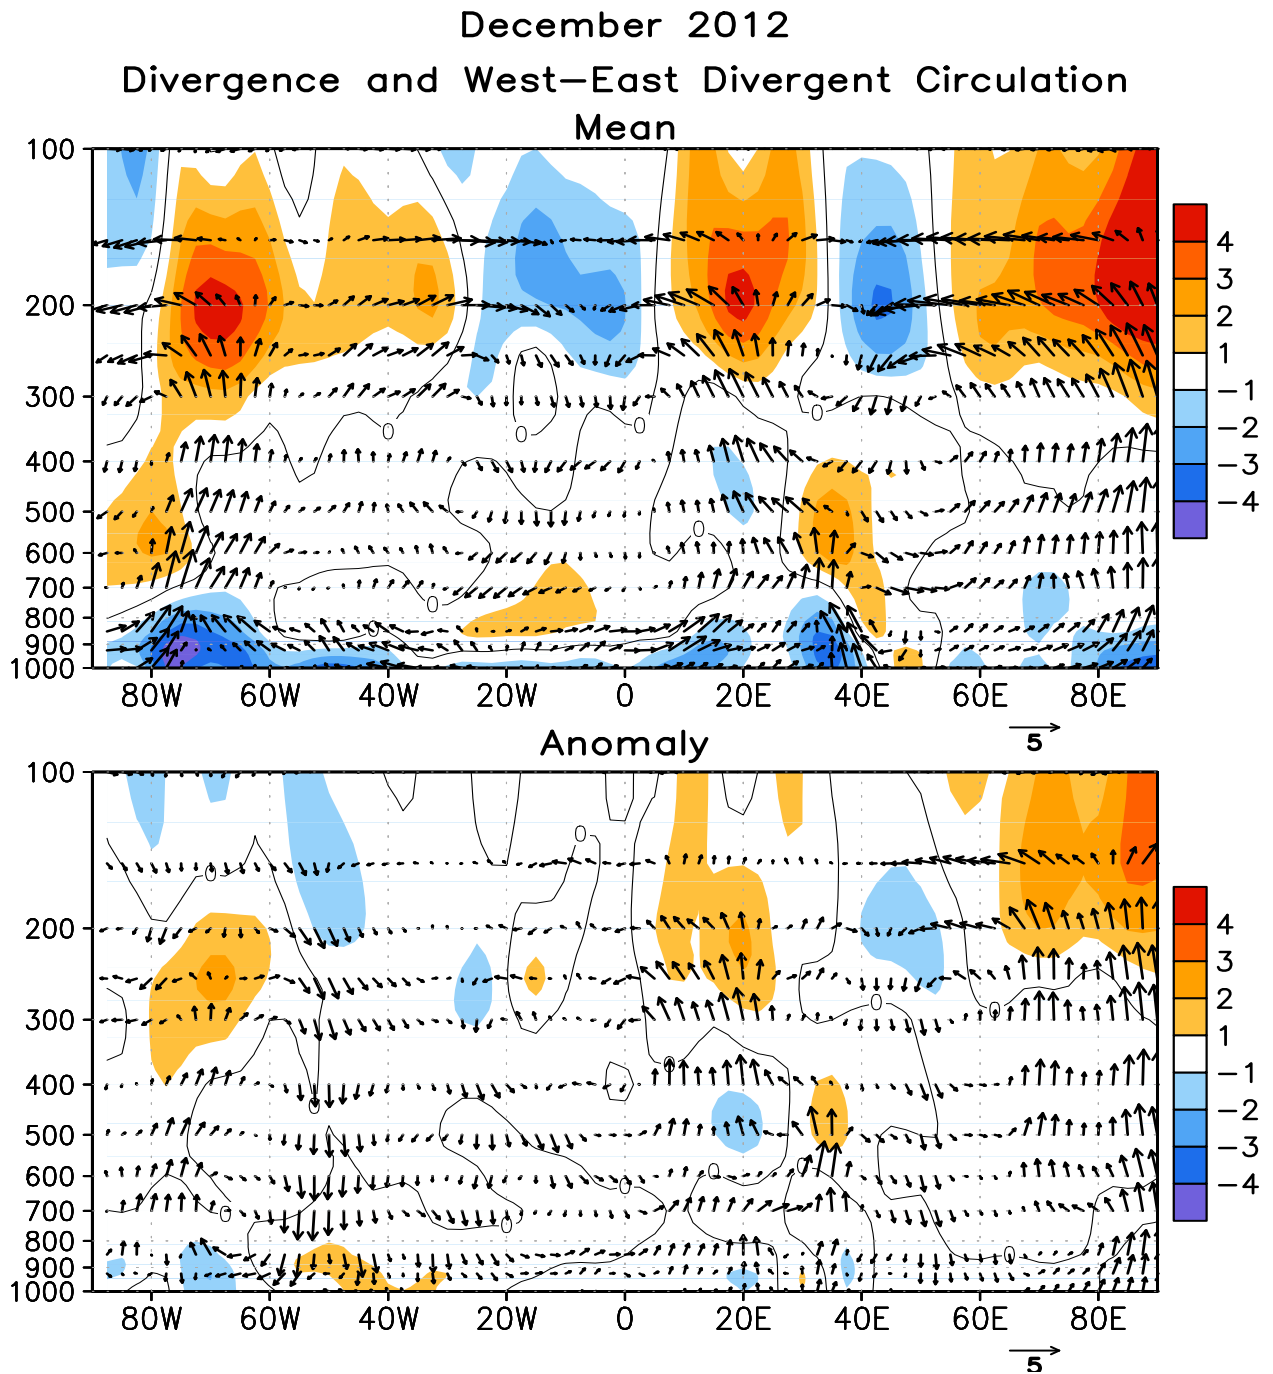

FIGURE T30. Pressure-longitude section (80W-100E) of the mean (top) and anomalous (bottom) divergence (contour interval is  $1 \times 10^{-6} \text{ s}^{-1}$ ) and divergent circulation averaged between 5N-5S. The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the zonal wind. Red shading and solid contours denote divergence (top) and anomalous divergence (bottom). Blue shading and dashed contours denote convergence (top) and anomalous convergence (bottom). Anomalies are departures from the 1981-2010 base period monthly means.

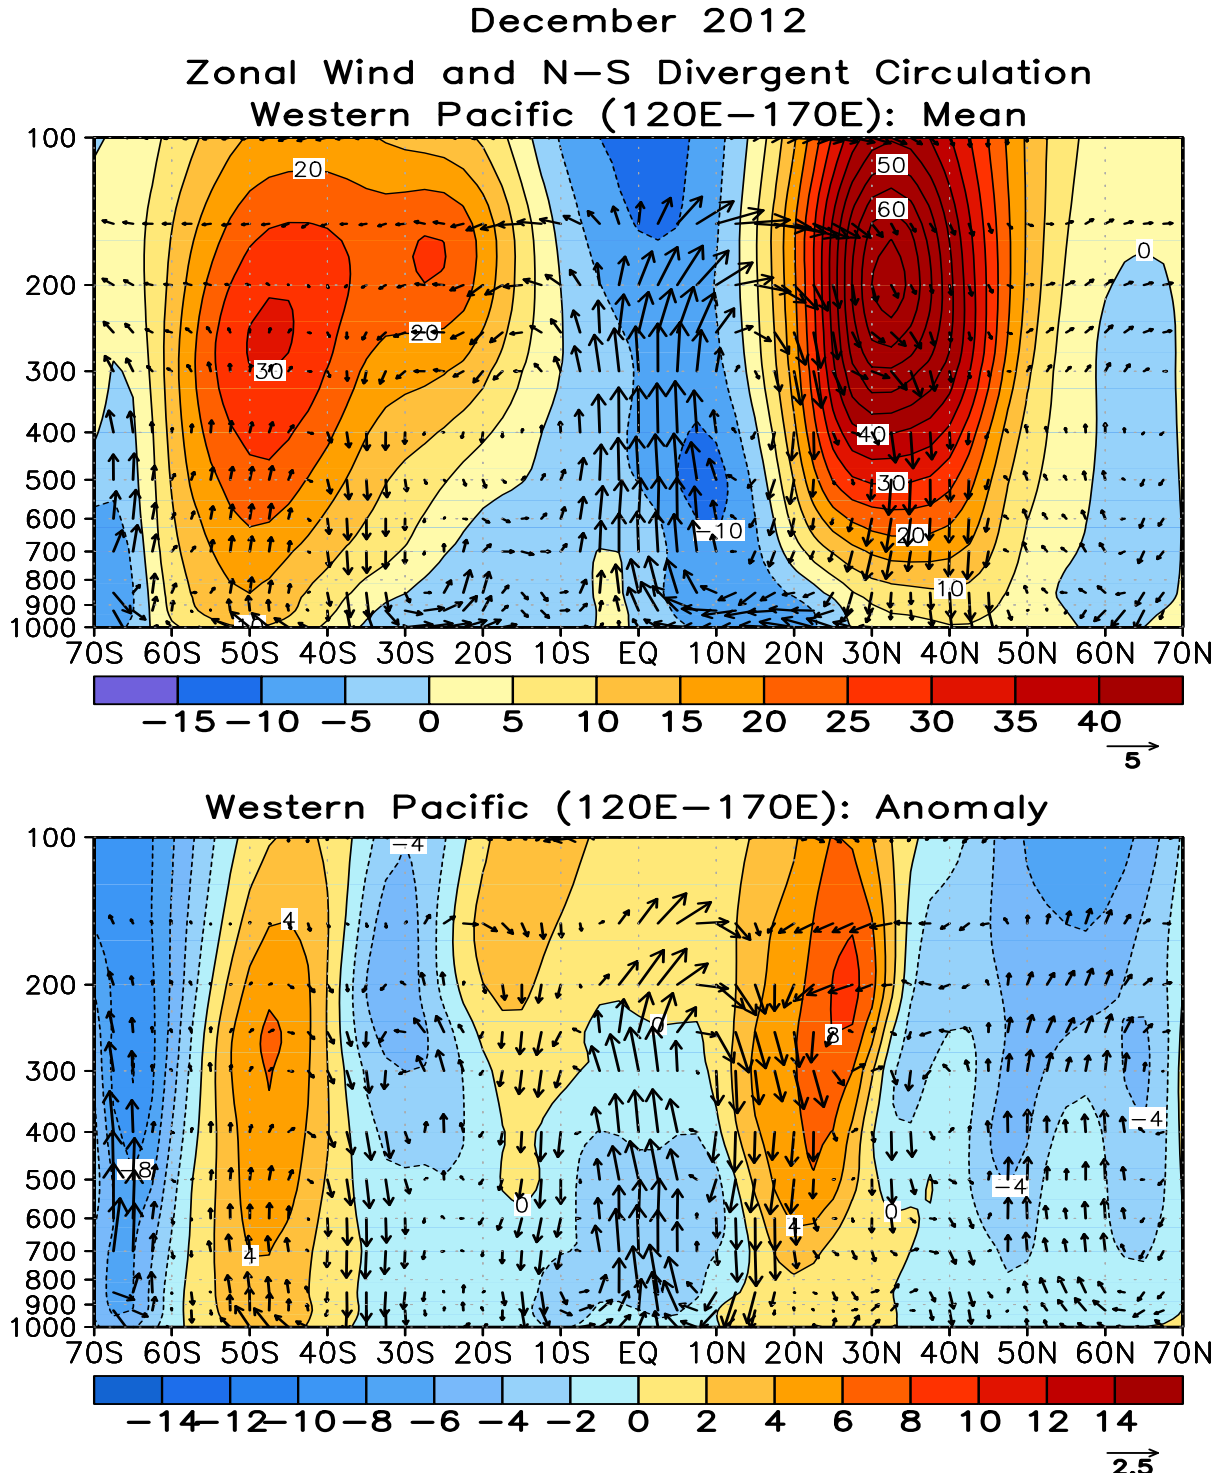

FIGURE T31. Pressure-latitude section of the mean (top) and anomalous (bottom) zonal wind ( $\text{m s}^{-1}$ ) and divergent circulation averaged over the west Pacific sector (120E–170E). The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the meridional wind. Red shading and solid contours denote a westerly (top) or anomalous westerly (bottom) zonal wind. Blue shading and dashed contours denote an easterly (top) or anomalous easterly (bottom) zonal wind. Anomalies are departures from the 1981–2010 base period monthly means.

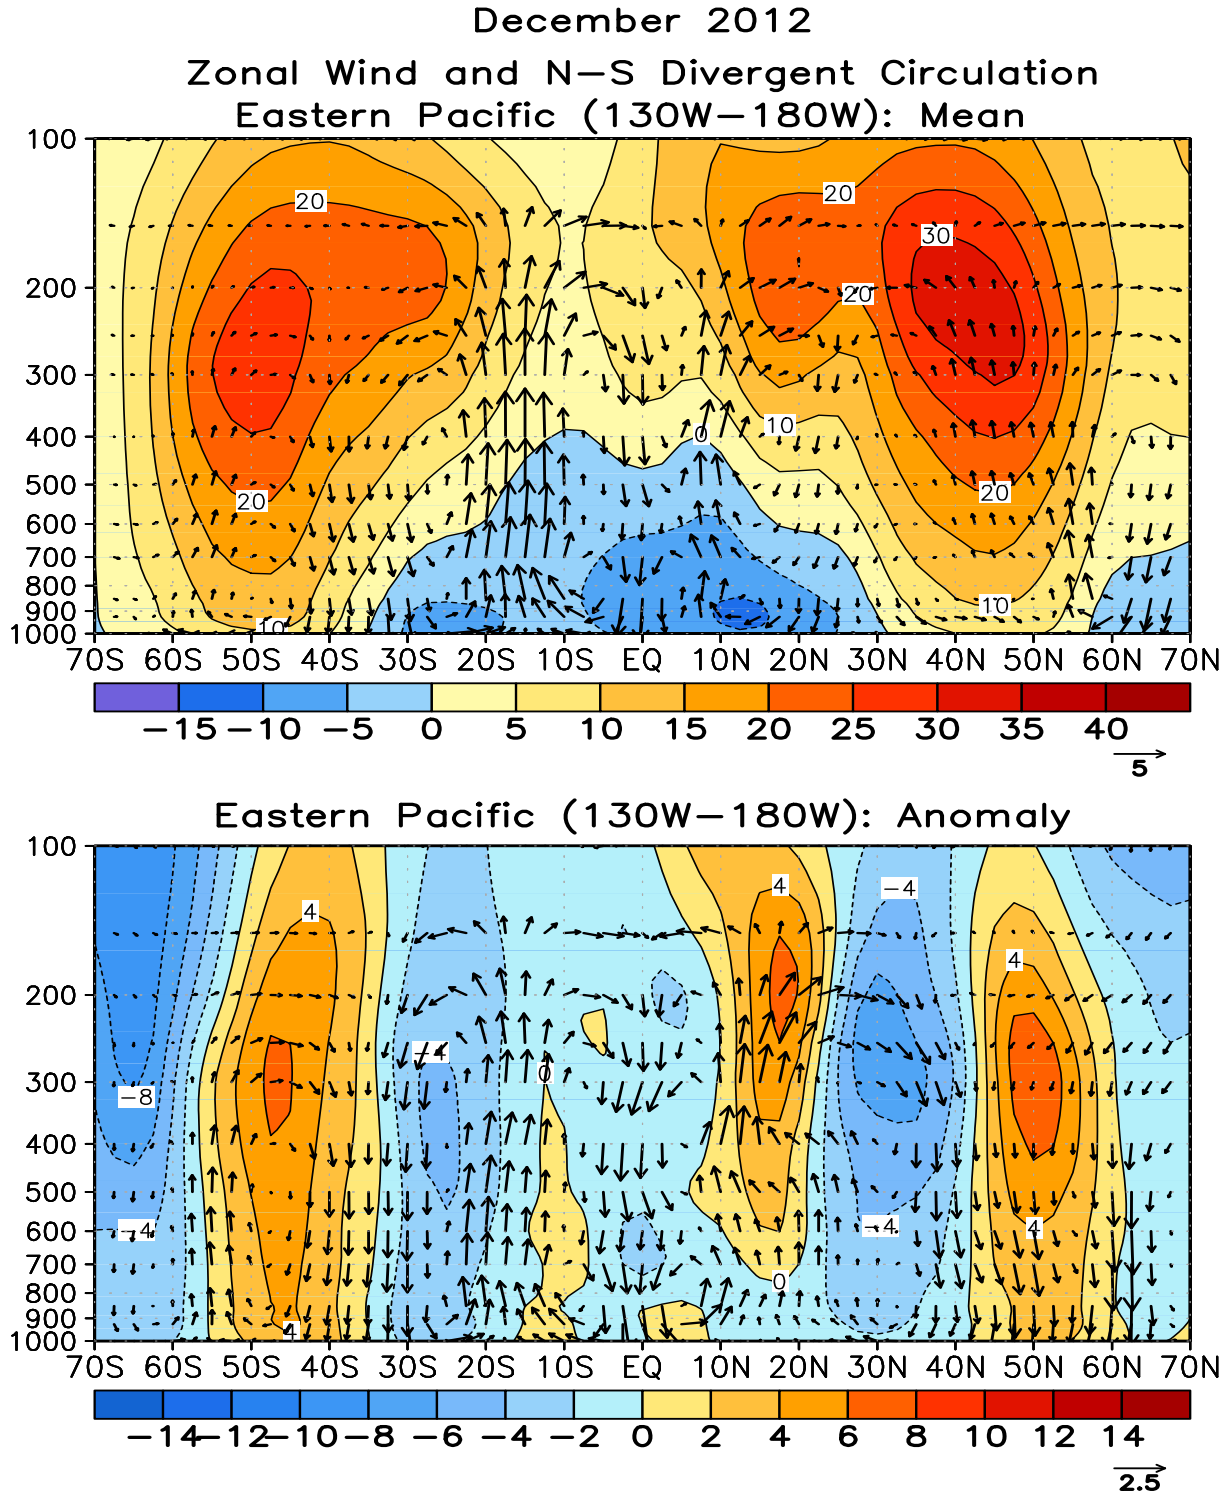

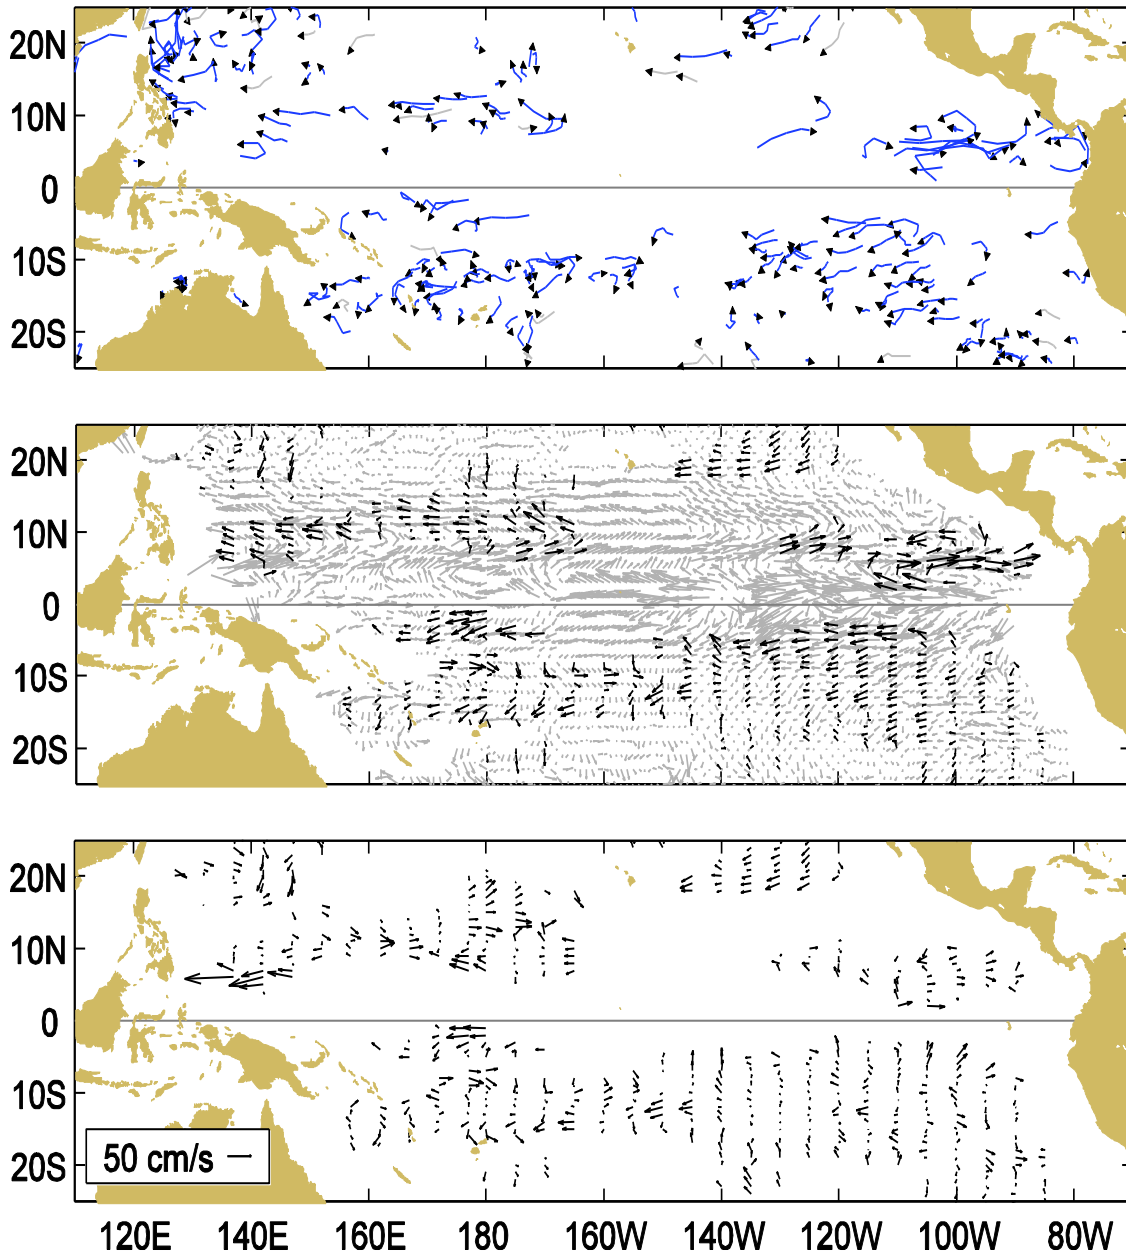

FIGURE T32. Pressure-latitude section of the mean (top) and anomalous (bottom) zonal wind ( $\text{m s}^{-1}$ ) and divergent circulation averaged over the central Pacific sector (130W-180W). The divergent circulation is represented by vectors of combined pressure vertical velocity and the divergent component of the meridional wind. Red shading and solid contours denote a westerly (top) or anomalous westerly (bottom) zonal wind. Blue shading and dashed contours denote an easterly (top) or anomalous easterly (bottom) zonal wind. Anomalies are departures from the 1981-2010 base period monthly means.

During December 2012, 315 satellite-tracked surface drifting buoys, 61% with subsurface drogues attached for measuring mixed layer currents, were reporting from the tropical Pacific. In the eastern Pacific, the NECC was approximately 20 cm/s weaker than normal climatological conditions.

**Figure A1.1 Top:** Movements of drifting buoys in the tropical Pacific Ocean during April 2005. The linear segments of each trajectory represent a one week displacement. Trajectories of buoys which have lost their subsurface drogues are gray; those with drogues are black.

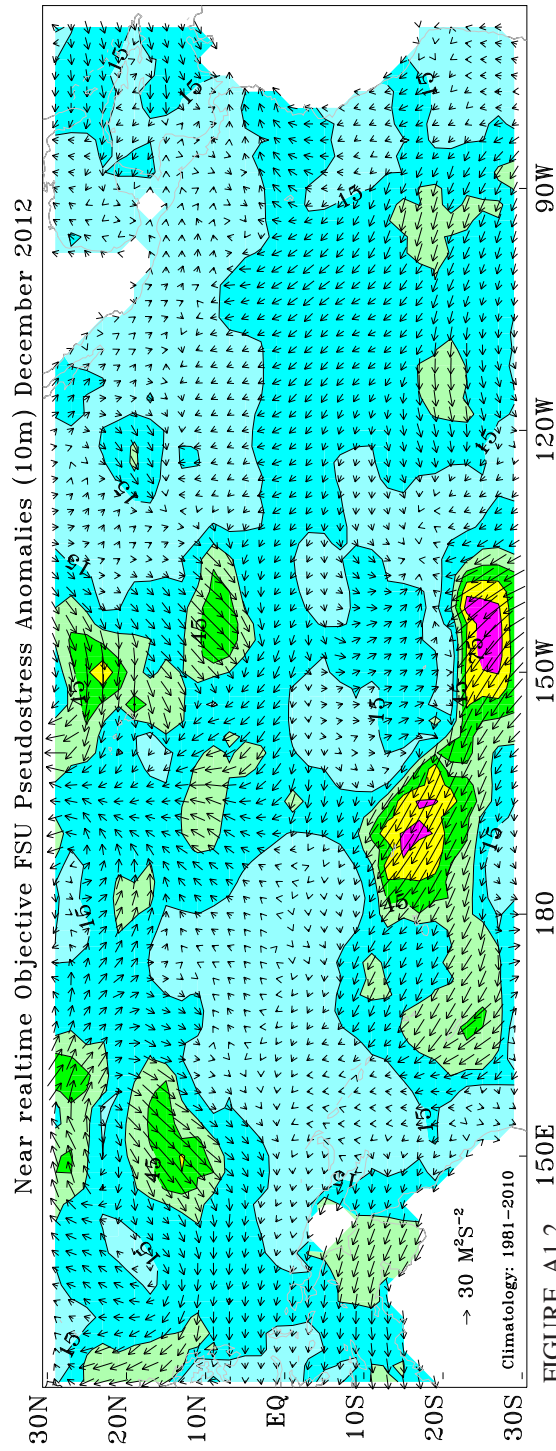

FIGURE A1.2. FSU SURFACE PSEUDO-STRESS VECTORS AND ANOMALIES: December 2012. Pseudo-stress vectors (top) are objectively analyzed from ship and buoy winds on a  $2^\circ$  grid. Ship and buoy data are independently weighted and the background field is created from the data. Contour interval of the vector magnitudes is  $20 M^2S^{-2}$ . Anomalies (bottom) are departures from 1981-2010 mean. The contour interval is  $15 M^2S^{-2}$ . For more information, please visit our web site at <http://www.coaps.fsu.edu/RVSMDC/html/winds.shtml>. ## Forecast Forum

The canonical correlation analysis (CCA) forecast of SST in the central Pacific (Barnett et al. 1988, *Science*, **241**, 192196; Barnston and Ropelewski 1992, *J. Climate*, **5**, 13161345), is shown in **Figs. F1 and F2**. This forecast is produced routinely by the Prediction Branch of the Climate Prediction Center. The predictions from the National Centers for Environmental Prediction (NCEP) Coupled Forecast System Model (CFS03) are presented in **Figs. F3 and F4a, F4b**. Predictions from the Markov model (Xue, et al. 2000: *J. Climate*, **13**, 849871) are shown in **Figs. F5 and F6**. Predictions from the latest version of the LDEO model (Chen et al. 2000: *Geophys. Res. Let.*, **27**, 25852587) are shown in **Figs. F7 and F8**. Predictions using linear inverse modeling (Penland and Magorian 1993: *J. Climate*, **6**, 10671076) are shown in **Figs. F9 and F10**. Predictions from the Scripps / Max Planck Institute (MPI) hybrid coupled model (Barnett et al. 1993: *J. Climate*, **6**, 15451566) are shown in **Fig. F11**. Predictions from the ENSOCLIPER statistical model (Knaff and Landsea 1997, *Wea. Forecasting*, **12**, 633652) are shown in **Fig. F12**. Niño 3.4 predictions are summarized in **Fig. F13**, provided by the Forecasting and Prediction Research Group of the IRI.

The CPC and the contributors to the **Forecast Forum** caution potential users of this predictive information that they can expect only modest skill.

**ENSO Alert System Status:** [Not Active](#)

## Outlook

ENSO-neutral is favored through Northern Hemisphere spring 2013.

## Discussion

ENSO-neutral conditions continued during December 2012. Equatorial sea surface temperature (SST) anomalies were positive in the western Pacific, near zero in the central Pacific, and slightly negative in much of the eastern Pacific (Fig. T18). This SST anomaly pattern is also reflected in the Niño indices (Table T2). The oceanic heat content (average temperature in the upper 300m of the ocean) in the equatorial Pacific became slightly below average, with positive sub-surface temperature anomalies west of 165W and stronger negative anomalies in the east-central and eastern Pacific (Fig. T17). Upper- and lower-level zonal winds were near average across the tropical Pacific, and the Southern Oscillation Index was slightly negative (Figs. T20 and T21). Also, convection was suppressed over the central tropical Pacific and enhanced over western Indonesia (Fig. T25). Collectively, these oceanic and atmospheric features indicate ENSO-neutral conditions.

Model predictions favor near-average SST in the Niño-3.4 region from the Northern Hemisphere winter 2012-13 into summer 2013 (Figs. F1-F13). Because predictions through the April-June season are known to be less skillful, the forecasts for the summer carry limited confidence at this time. Thus, it is considered unlikely that an El Niño or La Niña will develop during the next several months, and ENSO-neutral is favored through Northern Hemisphere spring 2013.

Weekly updates of oceanic and atmospheric conditions are available on the Climate Prediction Center homepage ([El Niño/La Niña Current Conditions and Expert Discussions](#)).

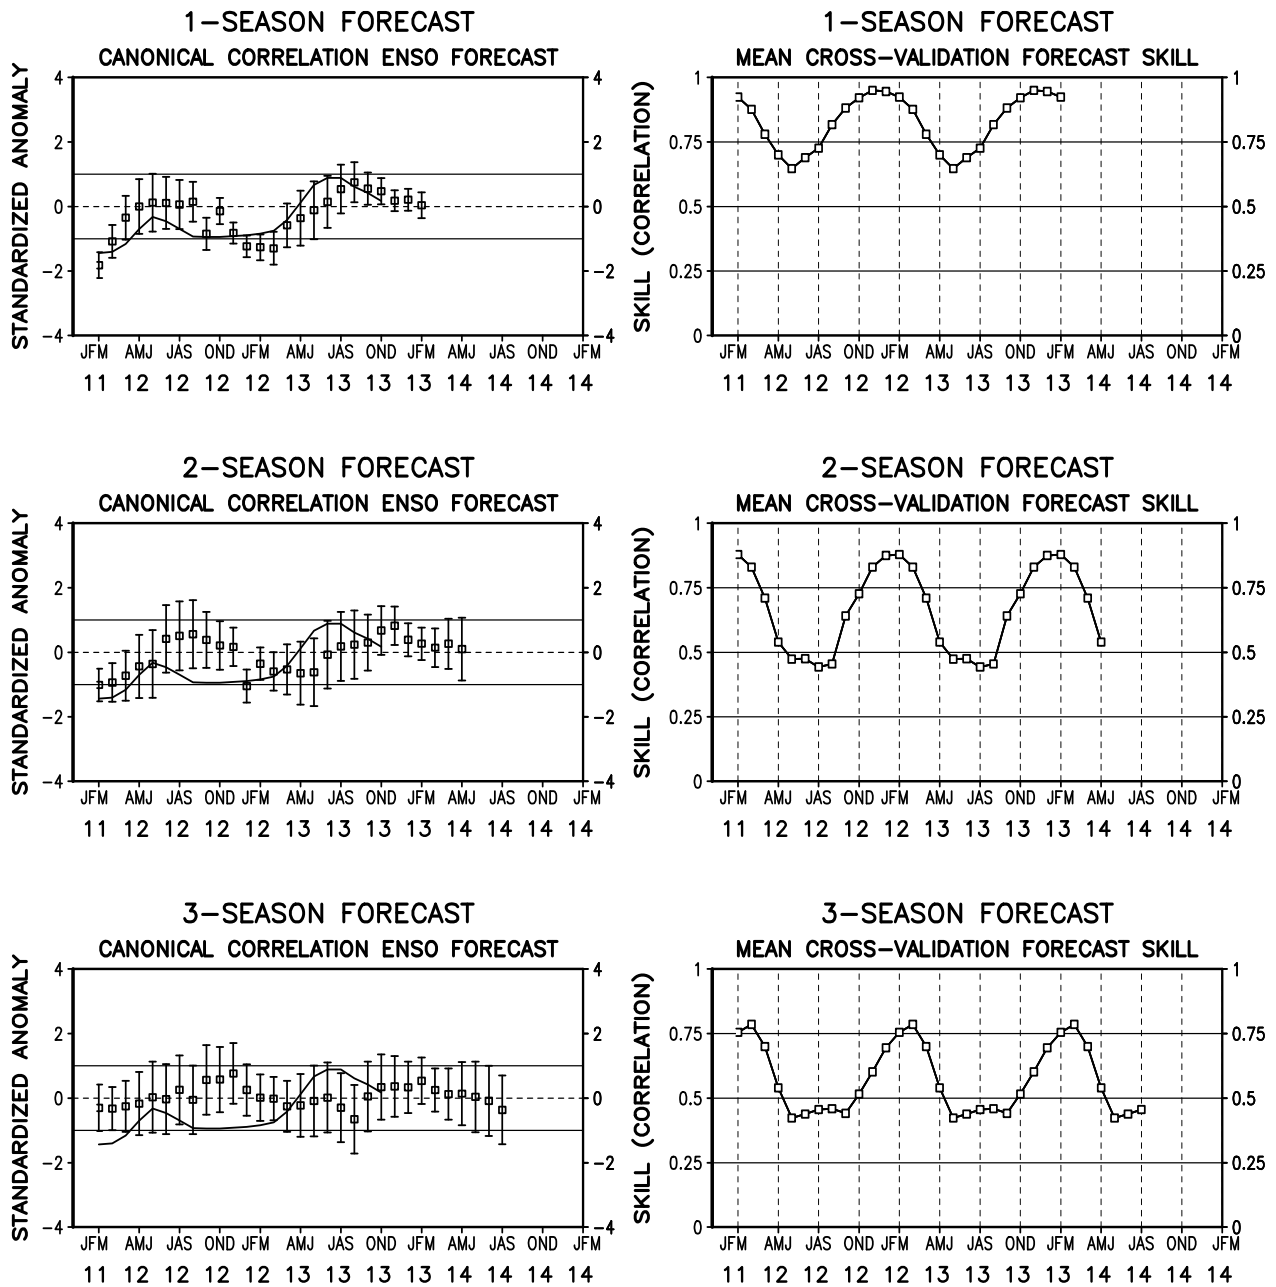

FIGURE F1. Canonical correlation analysis (CCA) sea surface temperature (SST) anomaly prediction for the central Pacific ( $5^{\circ}\text{N}$  to  $5^{\circ}\text{S}$ ,  $120^{\circ}\text{W}$  to  $170^{\circ}\text{W}$  (Barnston and Ropelewski, 1992, *J. Climate*, **5**, 1316-1345). The three plots on the left hand side are, from top to bottom, the 1-season, 2-season, and 3-season lead forecasts. The solid line in each forecast represents the observed SST standardized anomaly through the latest month. The small squares at the mid-points of the forecast bars represent the real-time CCA predictions based on the anomalies of quasi-global sea level pressure and on the anomalies of tropical Pacific SST, depth of the  $20^{\circ}\text{C}$  isotherm and sea level height over the prior four seasons. The vertical lines represent the one standard deviation error bars for the predictions based on past performance. The three plots on the right side are skills, corresponding to the predicted and observed SST. The skills are derived from cross-correlation tests from 1956 to present. These skills show a clear annual cycle and are inversely proportional to the length of the error bars depicted in the forecast time series.

## 0-4 SEASON LEAD FORECAST CANONICAL CORRELATION ENSO FORECAST

FIGURE F2. Canonical Correlation Analysis (CCA) forecasts of sea-surface temperature anomalies for the Niño 3.4 region (5N-5S, 120W-170W) for the upcoming five consecutive 3-month periods. Forecasts are expressed as standardized SST anomalies. The CCA predictions are based on anomaly patterns of SST, depth of the 20C isotherm, sea level height, and sea level pressure. Small squares at the midpoints of the vertical forecast bars represent the CCA predictions, and the bars show the one (thick) and two (thin) standard deviation errors. The solid continuous line represents the observed standardized three-month mean SST anomaly in the Niño 3.4 region up to the most recently available data.

Last update: Mon Jan 14 2013

Initial conditions: 3Jan2013–12Jan2013

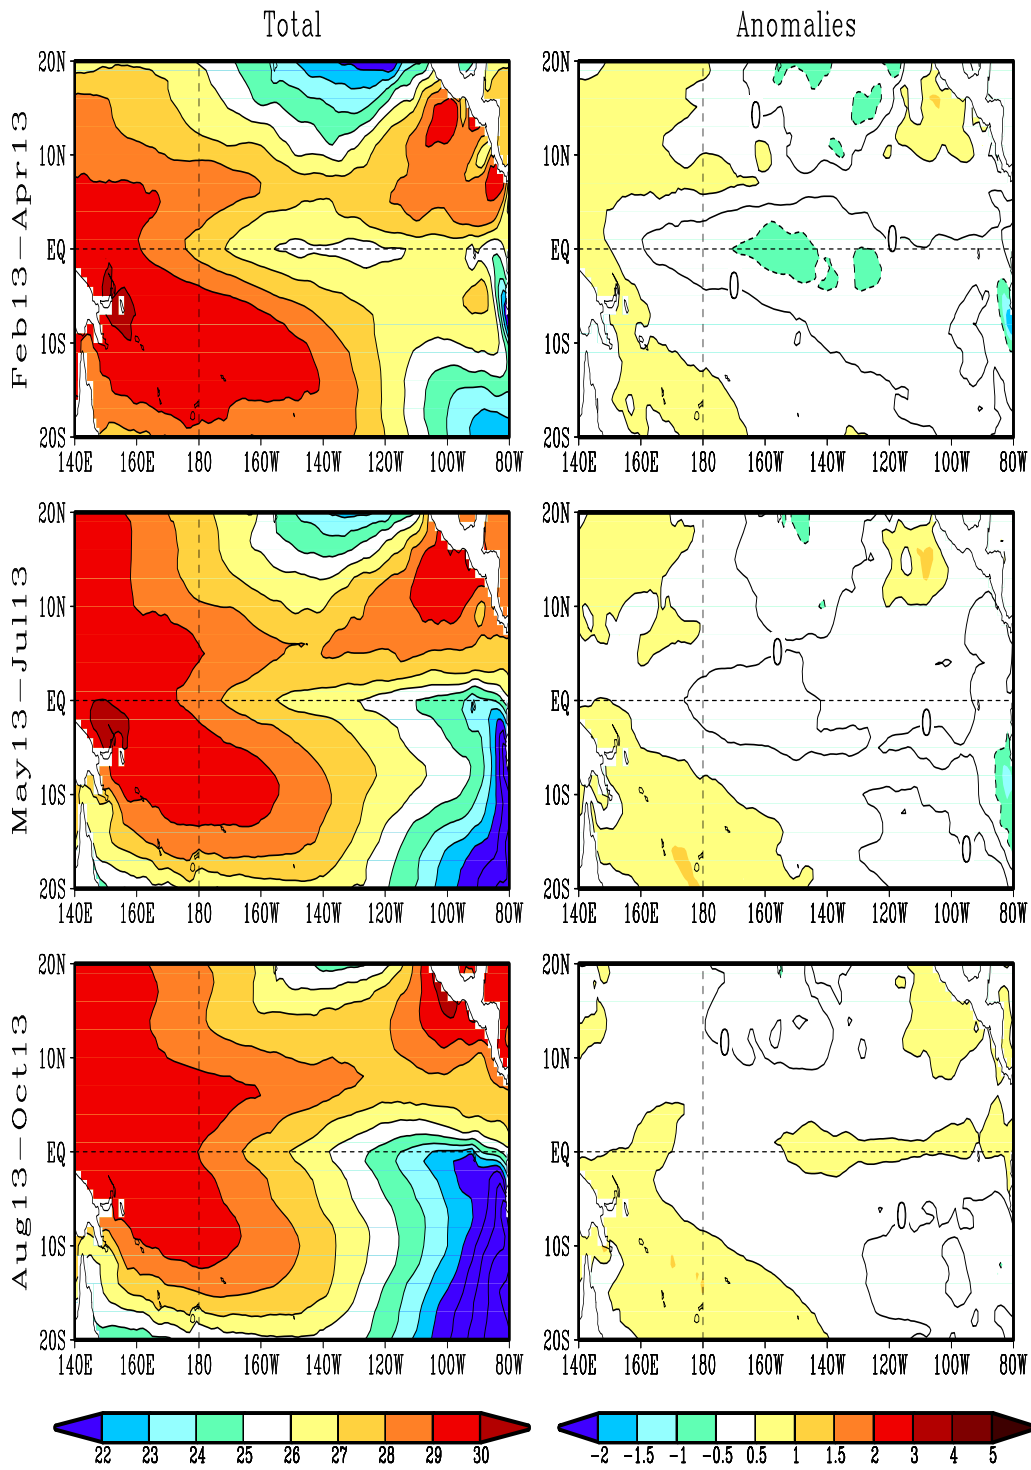

FIGURE F3. Predicted 3-month average sea surface temperature (left) and anomalies (right) from the NCEP Coupled Forecast System Model (CFS03). The forecasts consist of 40 forecast members. Contour interval is 1°C, with additional contours for 0.5°C and -0.5°C. Negative anomalies are indicated by dashed contours.

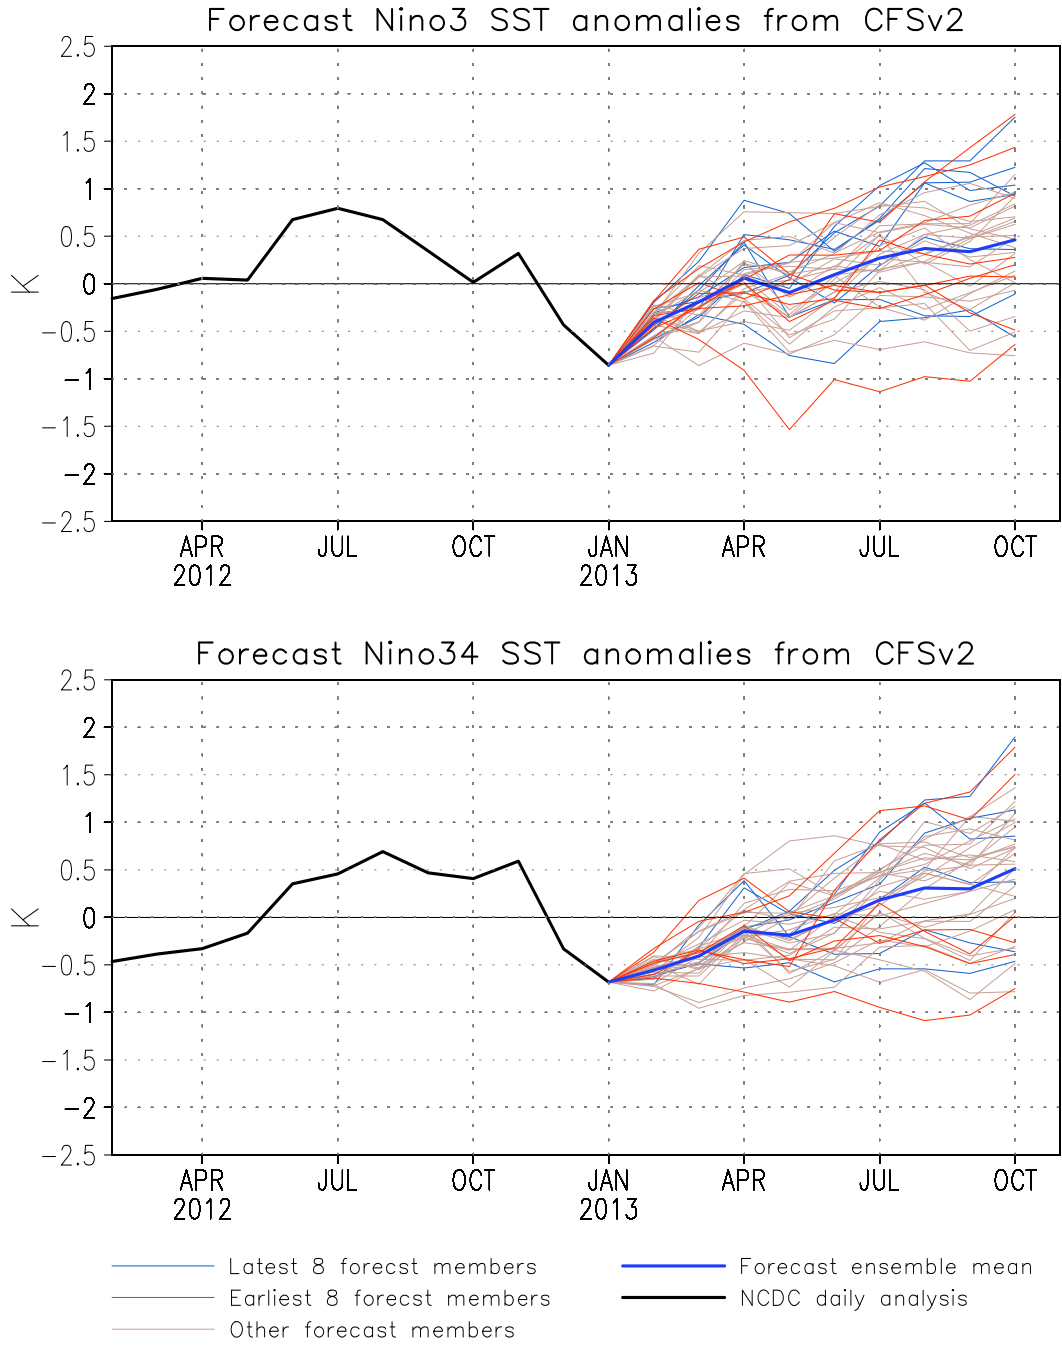

FIGURE F4. Predicted and observed sea surface temperature (SST) anomalies for the Nino 3 (top) and Nino 3.4 (bottom) regions from the NCEP Coupled Forecast System Model (CFS03). The forecasts consist of 40 forecast members. The ensemble mean of all 40 forecast members is shown by the blue line, individual members are shown by thin lines, and the observation is indicated by the black line. The Nino-3 region spans the eastern equatorial Pacific between 5N-5S, 150W-90W. The Nino 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W.

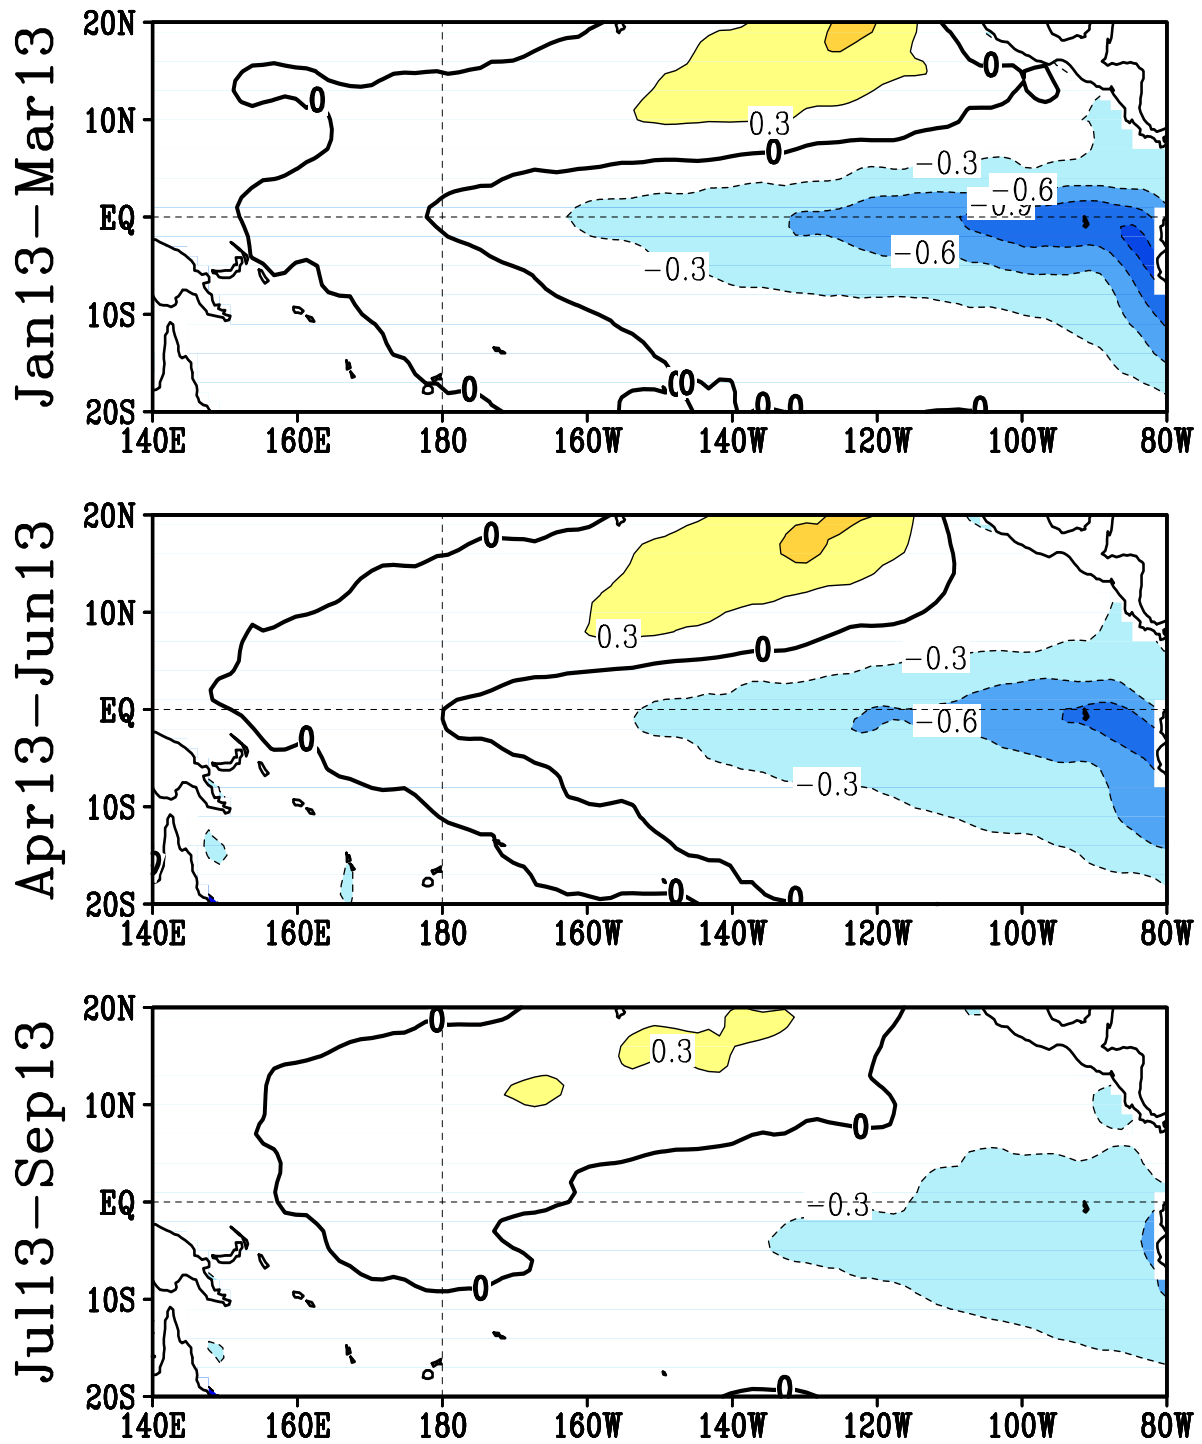

FIGURE F5. Predicted 3-month average sea surface temperature anomalies from the NCEP/CPC Markov model (Xue et al. 2000, *J. Climate*, **13**, 849-871). The forecast is initiated in DEC 2012 . Contour interval is 0.3C and negative anomalies are indicated by dashed contours. Anomalies are calculated relative to the 1971-2000 climatology.

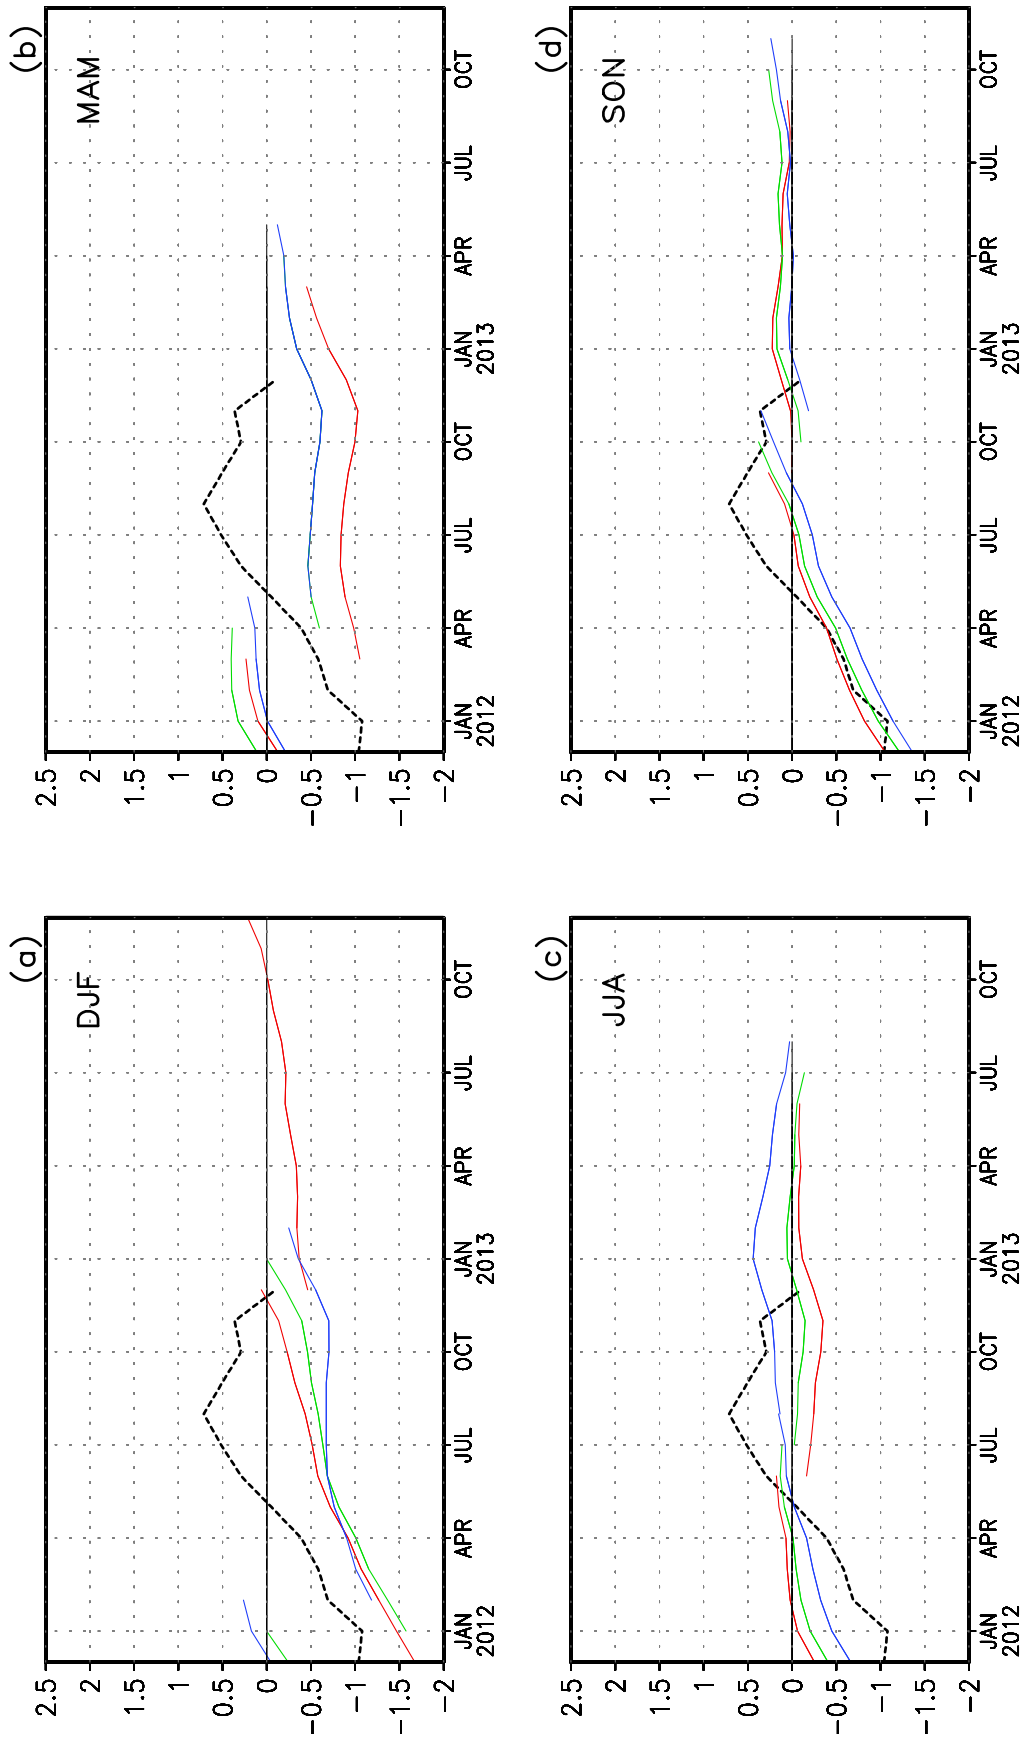

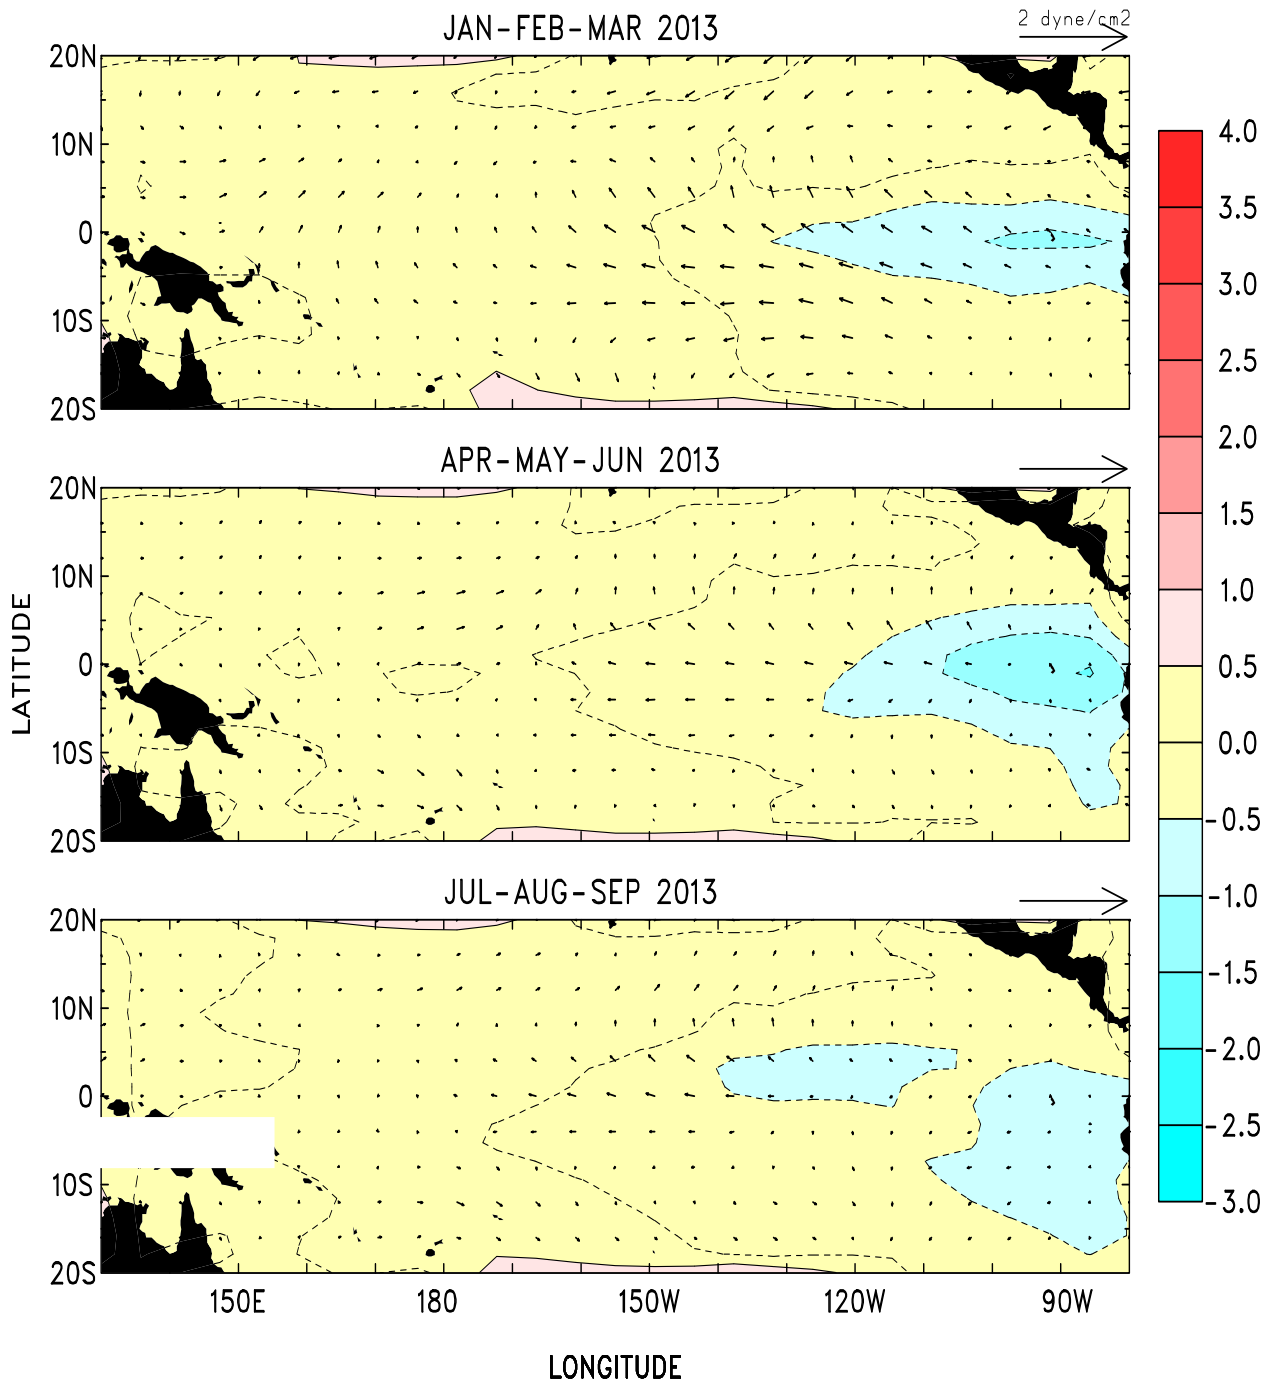

FIGURE F6. Time evolution of observed and predicted SST anomalies in the Niño 3.4 region (up to 12 lead months) by the NCEP/CPC Markov model (Xue et al. 2000, *J. Climate*, **13**, 849-871). Anomalies are calculated relative to the 1971-2000 climatology. Shown in each panel are the forecasts grouped by three consecutive starting months: (a) is for December, January, and February, (b) is for March, April, and May, (c) is for June, July, and August, and (d) is for September, October, and November. The observed Niño 3.4 SST anomalies are indicated by the black dashed lines. The Niño 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W.

# LDEO FORECASTS OF SST AND WIND STRESS ANOMALIES

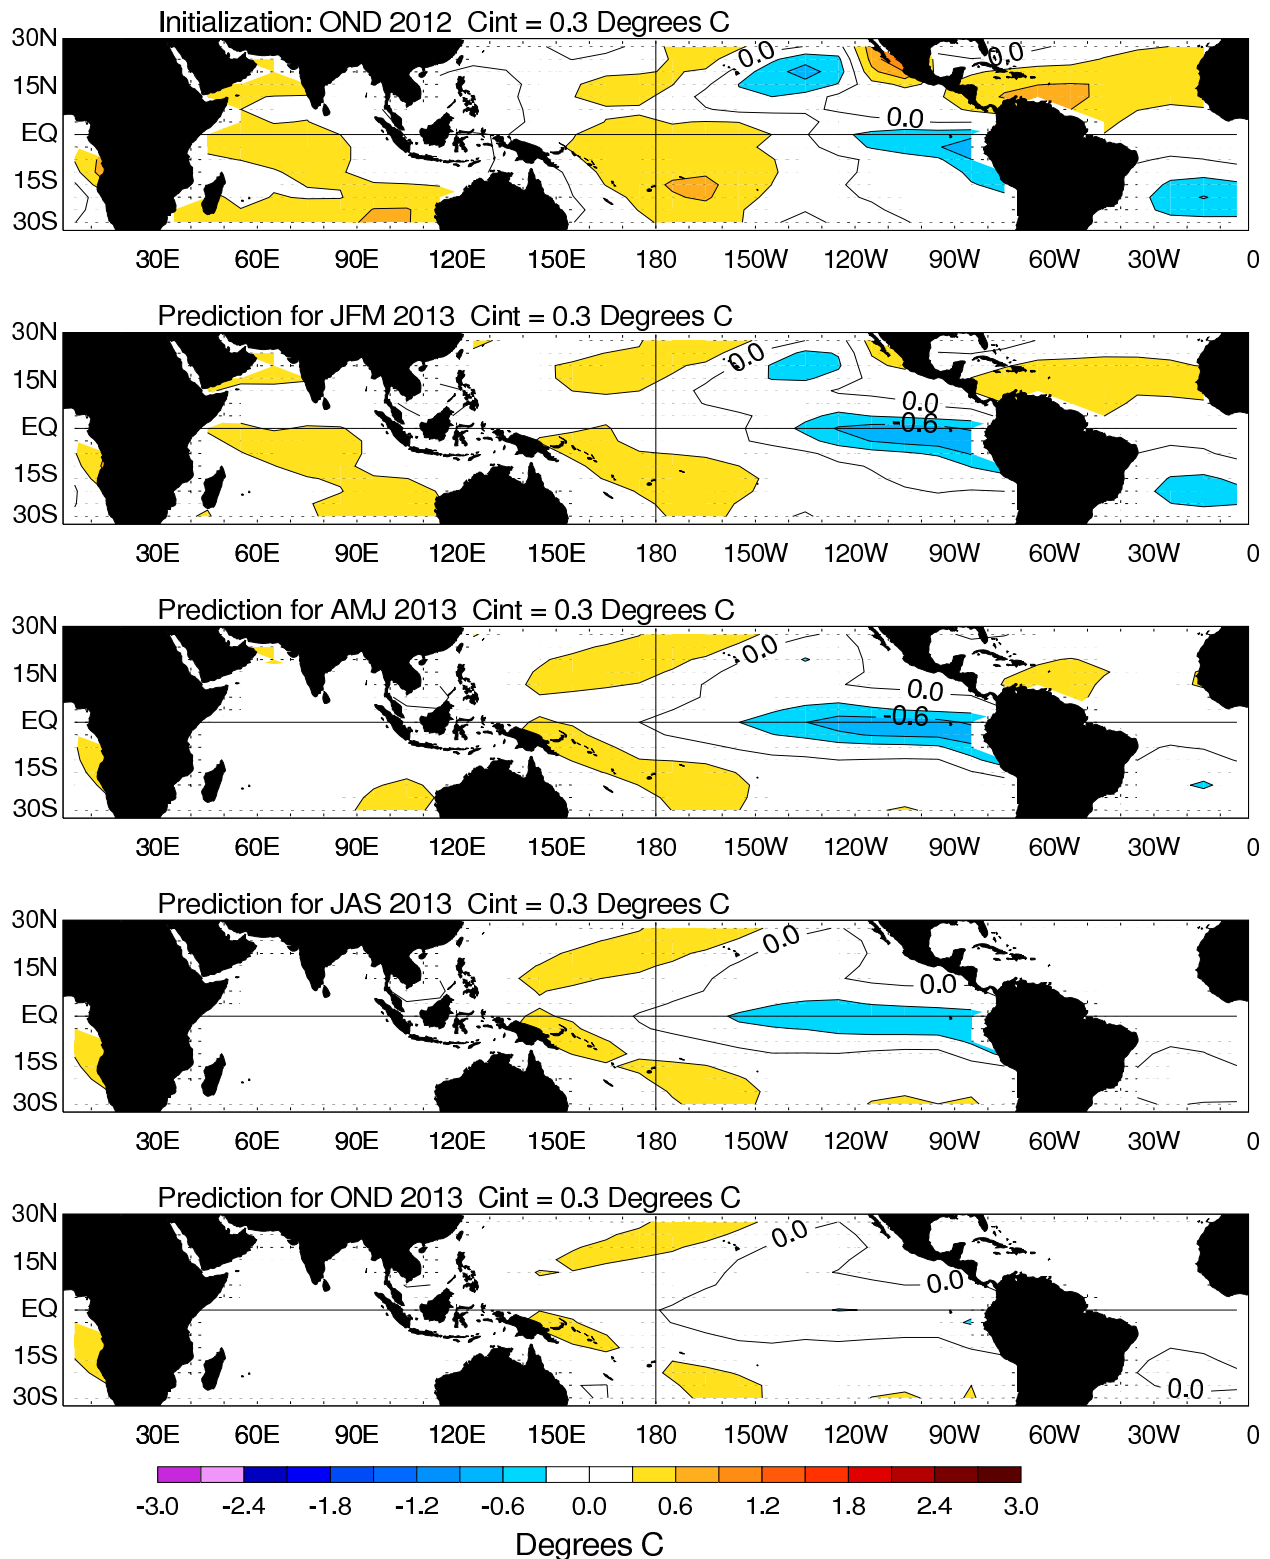

**FIGURE F7.** Forecasts of the tropical Pacific Predicted SST (shading) and vector wind anomalies for the next 3 seasons based on the LDEO model. Each forecast represents an ensemble average of 3 sets of predictions initialized during the last three consecutive months (see Figure F8).

## LDEO FORECASTS OF NINO3

**FIGURE F8.** LDEO forecasts of SST anomalies for the Nino 3 region using wind stresses obtained from (top) QuikSCAT, (middle) NCEP, and (bottom) Florida State Univ. (FSU), along with SSTs (obtained from NCEP), and sea surface height data (obtained from TOPEX/POSEIDON) data. Each thin blue line represents a 12-month forecast, initialized one month apart for the past 24 months. Observed SST anomalies are indicated by the thick red line. The Nino-3 region spans the eastern equatorial Pacific between 5N-5S, 150W-90W.

NOAA/ESRL PSD and CIRES/CDC Experimental Forecast

FIGURE F9. Forecast of tropical SST anomalies from the Linear Inverse Modeling technique of Penland and Magorian (1993: *J. Climate*, **6**, 1067-1076). The contour interval is 0.3C. Anomalies are calculated relative to the 1981-2010 climatology and are projected onto 20 leading EOFs.

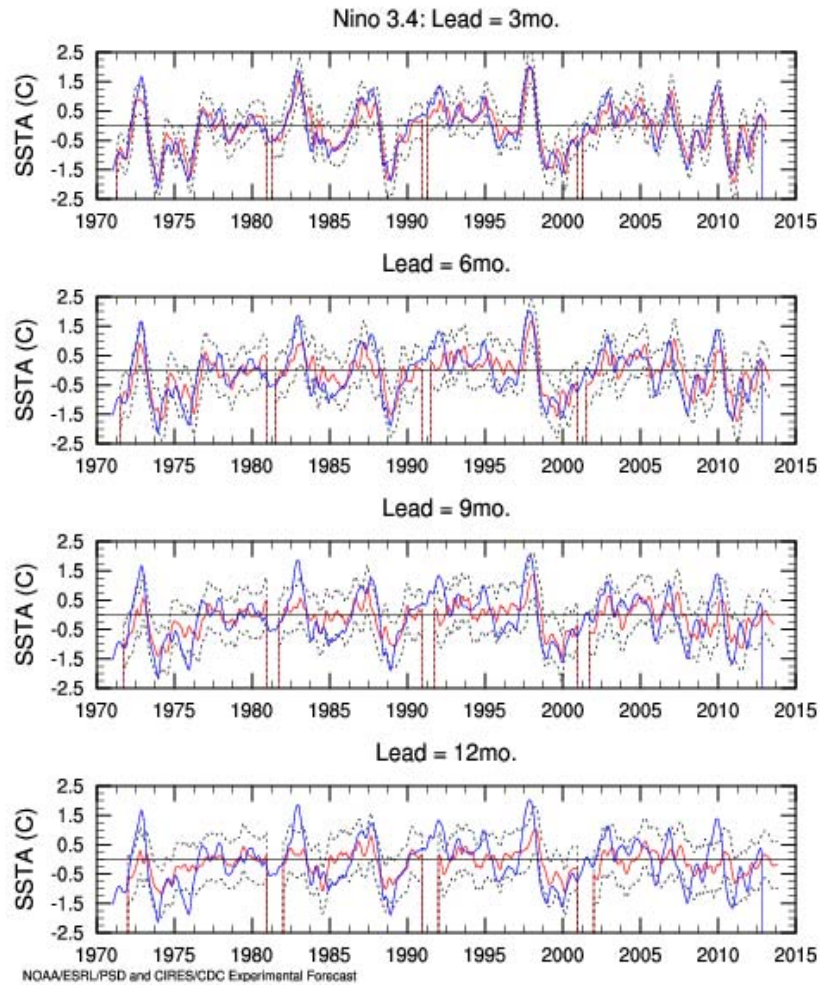

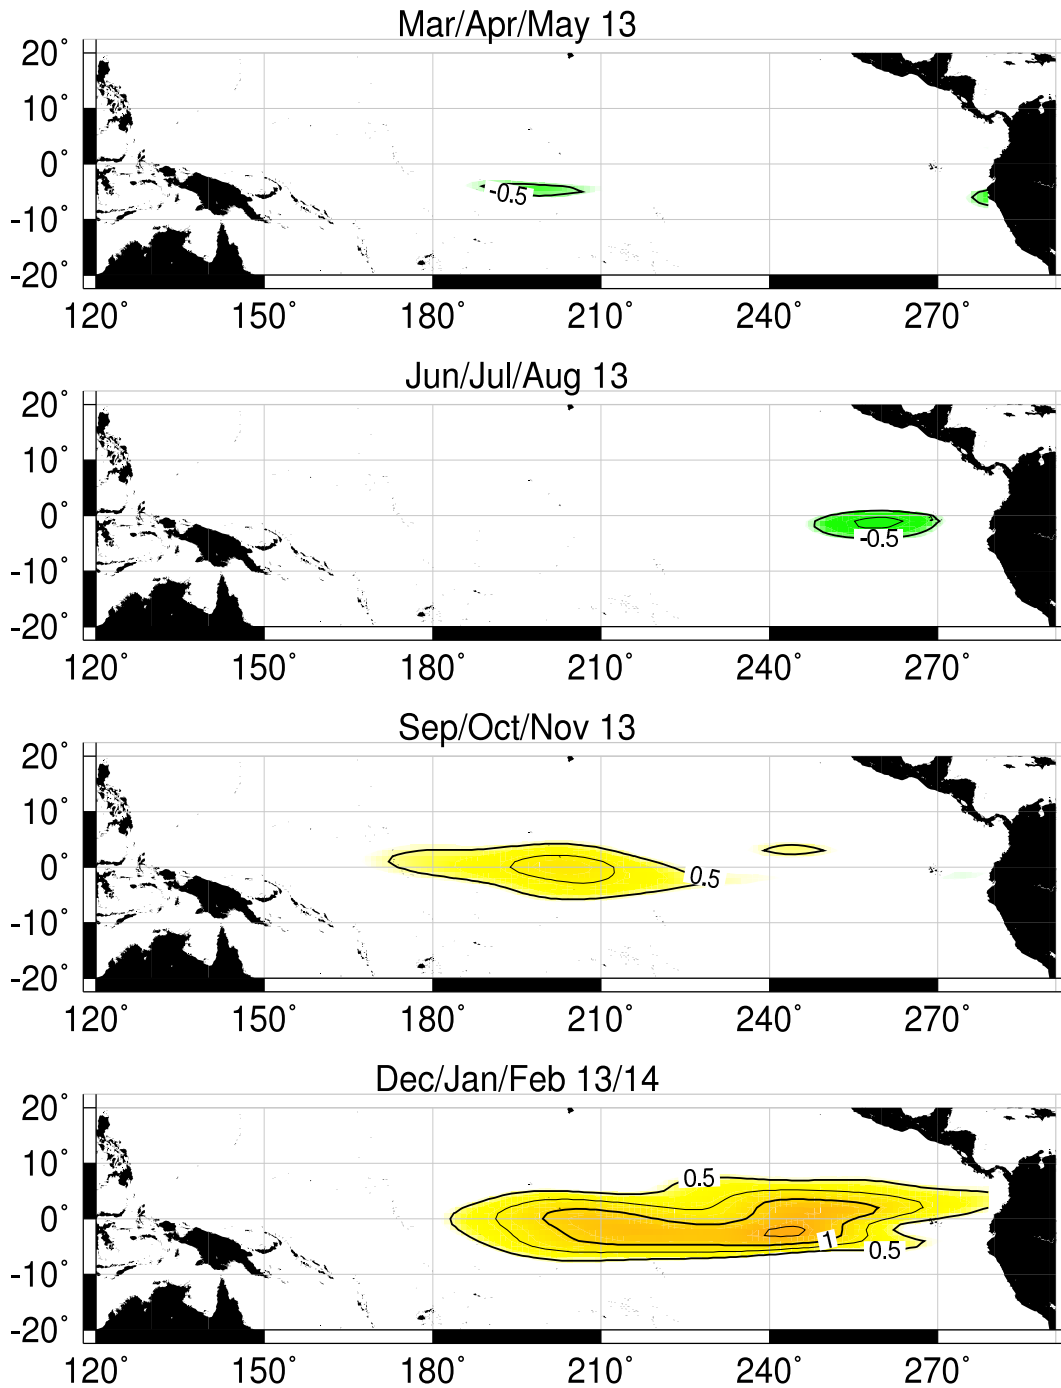

FIGURE F10. Predictions of Niño 3.4 SSTA (blue solid line) and verification (solid red line). The Niño3.4 Index was calculated in the area 6N-6S, 170W-120W. The 1980-2010 climatology was subtracted from ERSST data between 1950 and 2010, after which they were projected onto 20 EOFs containing 90% of the variance. Significant 1950-2010 trends were subtracted from the corresponding PCs, the forecast was made on the detrended anomalies, after which the trend was added to the forecast. The dotted lines indicate the one standard deviation confidence interval for the forecasts based on a perfect adherence to assumption.

# SIO/MPI HCM-T3.0 Tropical SST Anomaly Forecast, 02 Jan 2013

Forecast made with data thru 29 Dec 2012

David Pierce

FIGURE F11. SST anomaly forecast for the equatorial Pacific from the Hybrid Coupled Model (HCM) developed by the Scripps Institution of Oceanography and the Max-Planck Institut fuer Meteorologie.

FIGURE F12. ENSO-CLIPER statistical model forecasts of three-month average sea surface temperature anomalies (green lines, deg. C) in (top panel) the Nino 4 region (5N-5S, 160E-150W), (second panel) the Nino 3.4 region (5N-5S, 170W-120W), (third panel) the Nino 3 region (5N-5S, 150W-90W), and (fourth panel) the Nino 1+2 region (0-10S, 90W-80W) (Knaff and Landsea 1997, *Wea. Forecasting*, **12**, 633-652). Bottom panel shows predictions of the three-month standardized Southern Oscillation Index (SOI, green line). Horizontal bars on green line indicate the adjusted root mean square error (RMSE). The Observed three-month average values are indicated by the thick blue line. SST anomalies are departures from the 1981-2010 base period means, and the SOI is calculated from the 1951-1980 base period means.

## Mid-Dec 2012 Plume of Model ENSO Predictions

FIGURE F13. Time series of predicted sea surface temperature anomalies for the Nino 3.4 region (deg. C) from various dynamical and statistical models for nine overlapping 3-month periods. The Nino 3.4 region spans the east-central equatorial Pacific between 5N-5S, 170W-120W. Figure provided by the International Research Institute (IRI).

## Extratropical Highlights – December 2012

### 1. Northern Hemisphere

The 500-hPa circulation during December featured above-average heights near the Aleutian Islands, across eastern Canada, Greenland and Scandinavia. Below-average heights were present over western North America, across the east-central North Atlantic and Europe, and over the middle latitudes of central and eastern Asia (Fig. E9). This overall pattern projected onto a strong positive phase of the Scandinavia teleconnection pattern (Fig. E7, Table E1). It also projected onto continuing negative phases (three months) of the West Pacific and Pacific/ North America teleconnection patterns, and onto the negative phase of the Tropical/ Northern Hemisphere pattern.

The main land-surface temperature signals during December included above-average temperatures across central and eastern North America, and below-average temperatures in Alaska and much of Eurasia (Fig. E1). The main precipitation signals included above-average totals in the northwestern and eastern U.S., northwestern and southeastern Europe, and eastern China, and below-average totals in the south-central U.S. (Fig. E3).

#### a. North America

The mean 500-hPa circulation during December featured above-average heights south of the Aleutian Islands and over eastern Canada, and below-average heights over western Canada (Figs. E9, E11). This pattern projected onto a continuing negative phase (three months) of the Pacific/ North America teleconnection pattern, and also onto the negative phase of the Tropical/ Northern Hemisphere pattern (Fig. E7, Table E1). These conditions reflected a nearly complete disappearance of the mean ridge normally located over western North America. They were also associated with a westward shift of the mean Hudson Bay trough axis to central North America. The resulting upper-level wind pattern reflected anomalous northwesterly flow into Alaska and anomalous southwesterly flow into the western U.S (Fig. E10).

These conditions were associated with above-average surface temperatures across the eastern half of North America, with most regions recording departures in the upper 70th percentile of occurrences (Fig. E1). In contrast, southwestern and eastern Alaska and northwestern Canada recorded below-average temperatures, with many areas recording departures in the lowest 30th percentile of occurrences.

Areas downstream of the mean trough axes recorded well above-average precipitation during December, including the U.S. Pacific Northwest and eastern U.S. (Fig. E3). Area-averaged totals in the Pacific Northwest reached the 90th percentile of occurrences, and were above average for a third straight month (Fig. E5).

In contrast, the south-central U.S. again recorded below-average monthly precipitation (Fig. E3), with large areas of Kansas, Oklahoma, and Texas recording totals less than 25% of normal (Fig. E6). This marks the eighth straight month of below-average precipitation in the Great Plains region (Fig. E5). As a result, much of the region continued to be impacted by extreme or exceptional drought. At the end of December, the “U.S. Drought Monitor” indicated exceptional drought from northern Texas northward to central South Dakota, including portions of eastern Wyoming and southeastern Colorado. Extreme drought persisted in northwestern Arkansas, northwestern Iowa,

and southwestern Minnesota.

#### b. North Atlantic/ Europe

The mean 500-hPa circulation during December featured a north-south dipole pattern of height anomalies, with above-average heights across eastern Canada, Greenland, and Scandinavia, and below-average heights over the east-central North Atlantic and Europe (Figs. E9). This pattern was associated with a complete disappearance of the Icelandic Low for a second straight month, and with a strong positive phase (+2.0) of the Scandinavia teleconnection pattern (Fig. E7, Table E1). It was also associated in northern Europe with enhanced jet stream winds, increased storminess (Fig. E13) and above-average precipitation (Fig. E3).

#### c. Asia

The 500-hPa height pattern during December featured an extensive area of negative height anomalies across central and eastern Asia (Fig. E9). Similar conditions were also present in November. In combination with the strong blocking ridge over Scandinavia, this pattern during December contributed to well below-average temperatures across central Asia, with many areas recording departures in the lowest 10th percentile of occurrences (Fig. E1). Also, eastern China recorded well above-average precipitation for a second straight month (Fig. E3), with area-averaged totals again reaching the 99th percentile of occurrences (Fig. E5).

## 2. Southern Hemisphere

The mean 500-hPa circulation during December featured above-average heights over the southeastern South Pacific Ocean and in the areas south of both Australia and South Africa, and generally below-average heights in the middle latitudes (Fig. E15)

Much of eastern Australia recorded anomalously warm (Fig. E1) and dry (Fig. E3) conditions in December, with portions of the northeast recording temperature departures in the upper 90th percentile of occurrences (Fig. E1).

The South African rainy season lasts from October to April. During December 2012, rainfall for the region as a whole was near average, with above-average totals in interior portions of southern Africa and below-average totals in extreme southern South Africa and Madagascar (Fig. E3). To date, the 2012-13 rainy season has been variable, with above-average totals in October, below-average totals in November, and near-average totals in December (Fig. E4).

TABLE E1-Standardized amplitudes of selected Northern Hemisphere teleconnection patterns for the most recent thirteen months (computational procedures are described in Fig. E7). Pattern names and abbreviations are North Atlantic Oscillation (NAO); East Atlantic pattern (EA); West Pacific pattern (WP); East Pacific - North Pacific pattern (EP-NP); Pacific/North American pattern (PNA); Tropical/Northern Hemisphere pattern (TNH); East Atlantic/Western Russia pattern (EATL/WRUS)-called Eurasia-2 pattern by Barnston and Livezey, 1987, *Mon. Wea. Rev.*, **115**, 1083-1126); Scandinavia pattern (SCAND-called Eurasia-1 pattern by Barnston and Livezey 1987); and Polar Eurasia pattern (POLEUR). No value is plotted for calendar months in which the pattern does not appear as a leading mode.

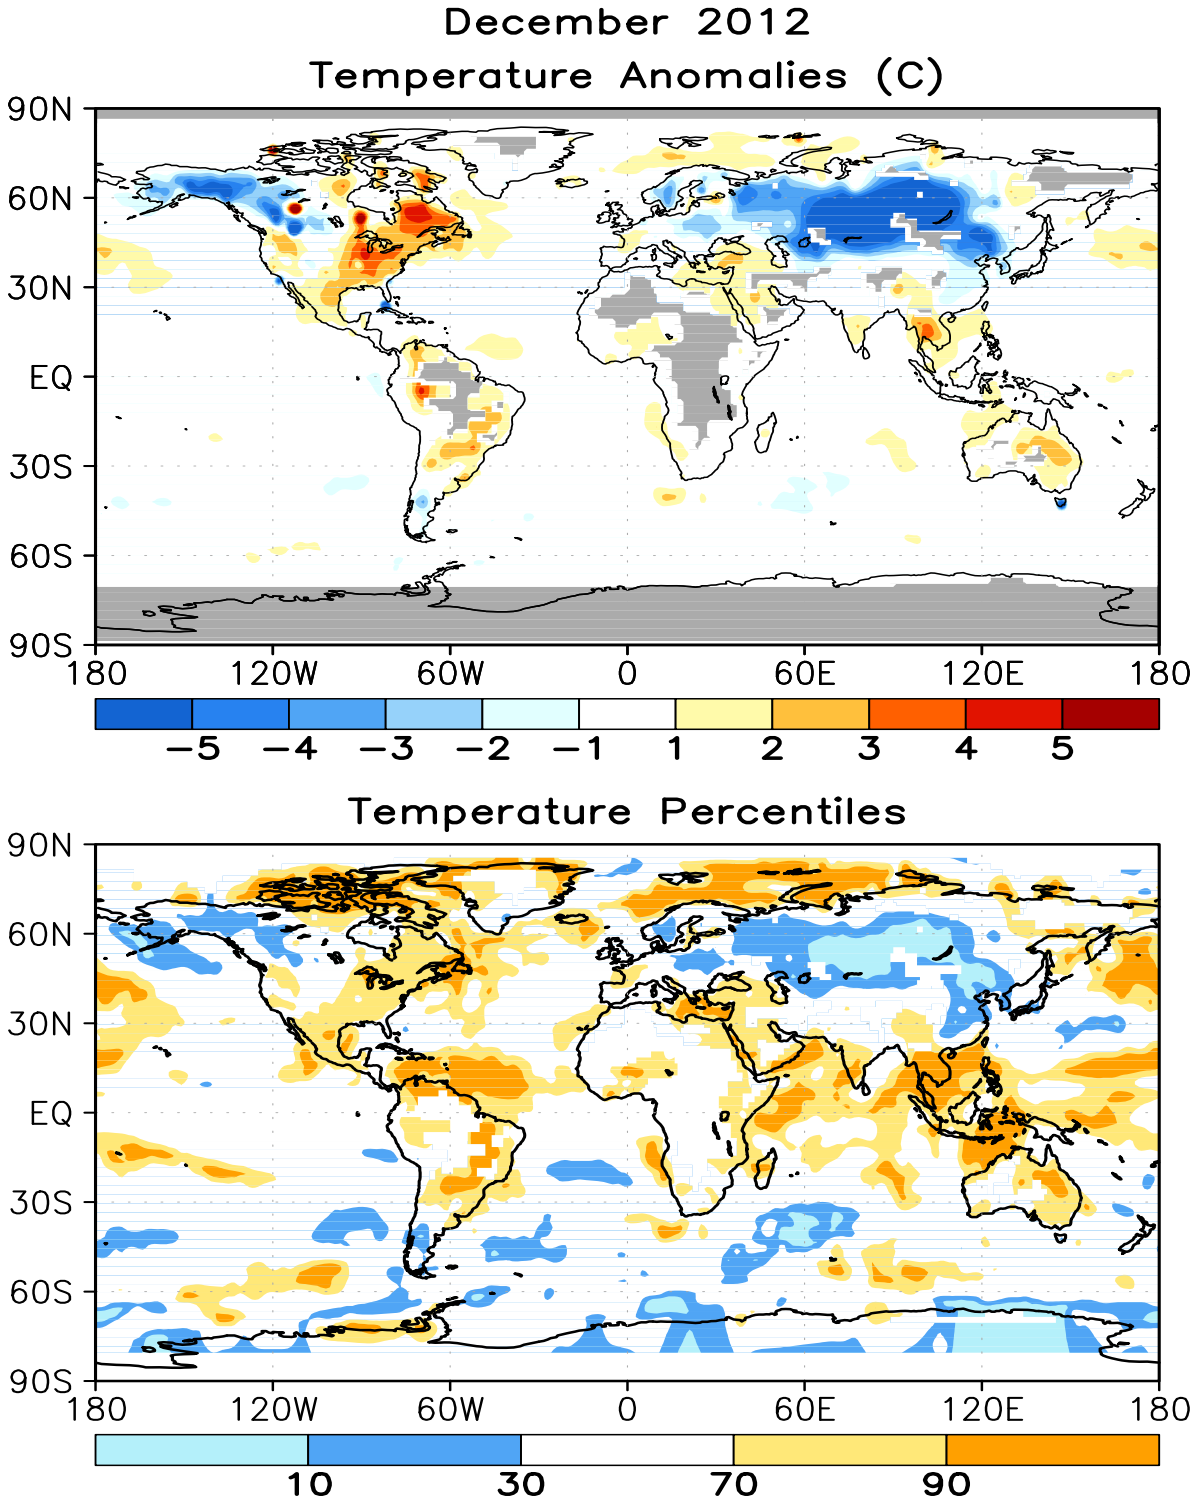

FIGURE E1. Surface temperature anomalies ( $^{\circ}\text{C}$ , top) and surface temperature expressed as percentiles of the normal (Gaussian) distribution fit to the 1981–2010 base period data (bottom) for DEC 2012. Analysis is based on station data over land and on SST data over the oceans (top). Anomalies for station data are departures from the 1981–2010 base period means, while SST anomalies are departures from the 1981–2010 adjusted OI climatology. (Smith and Reynolds 1998, *J. Climate*, **11**, 3320–3323). Regions with insufficient data for analysis in both figures are indicated by shading in the top figure only.

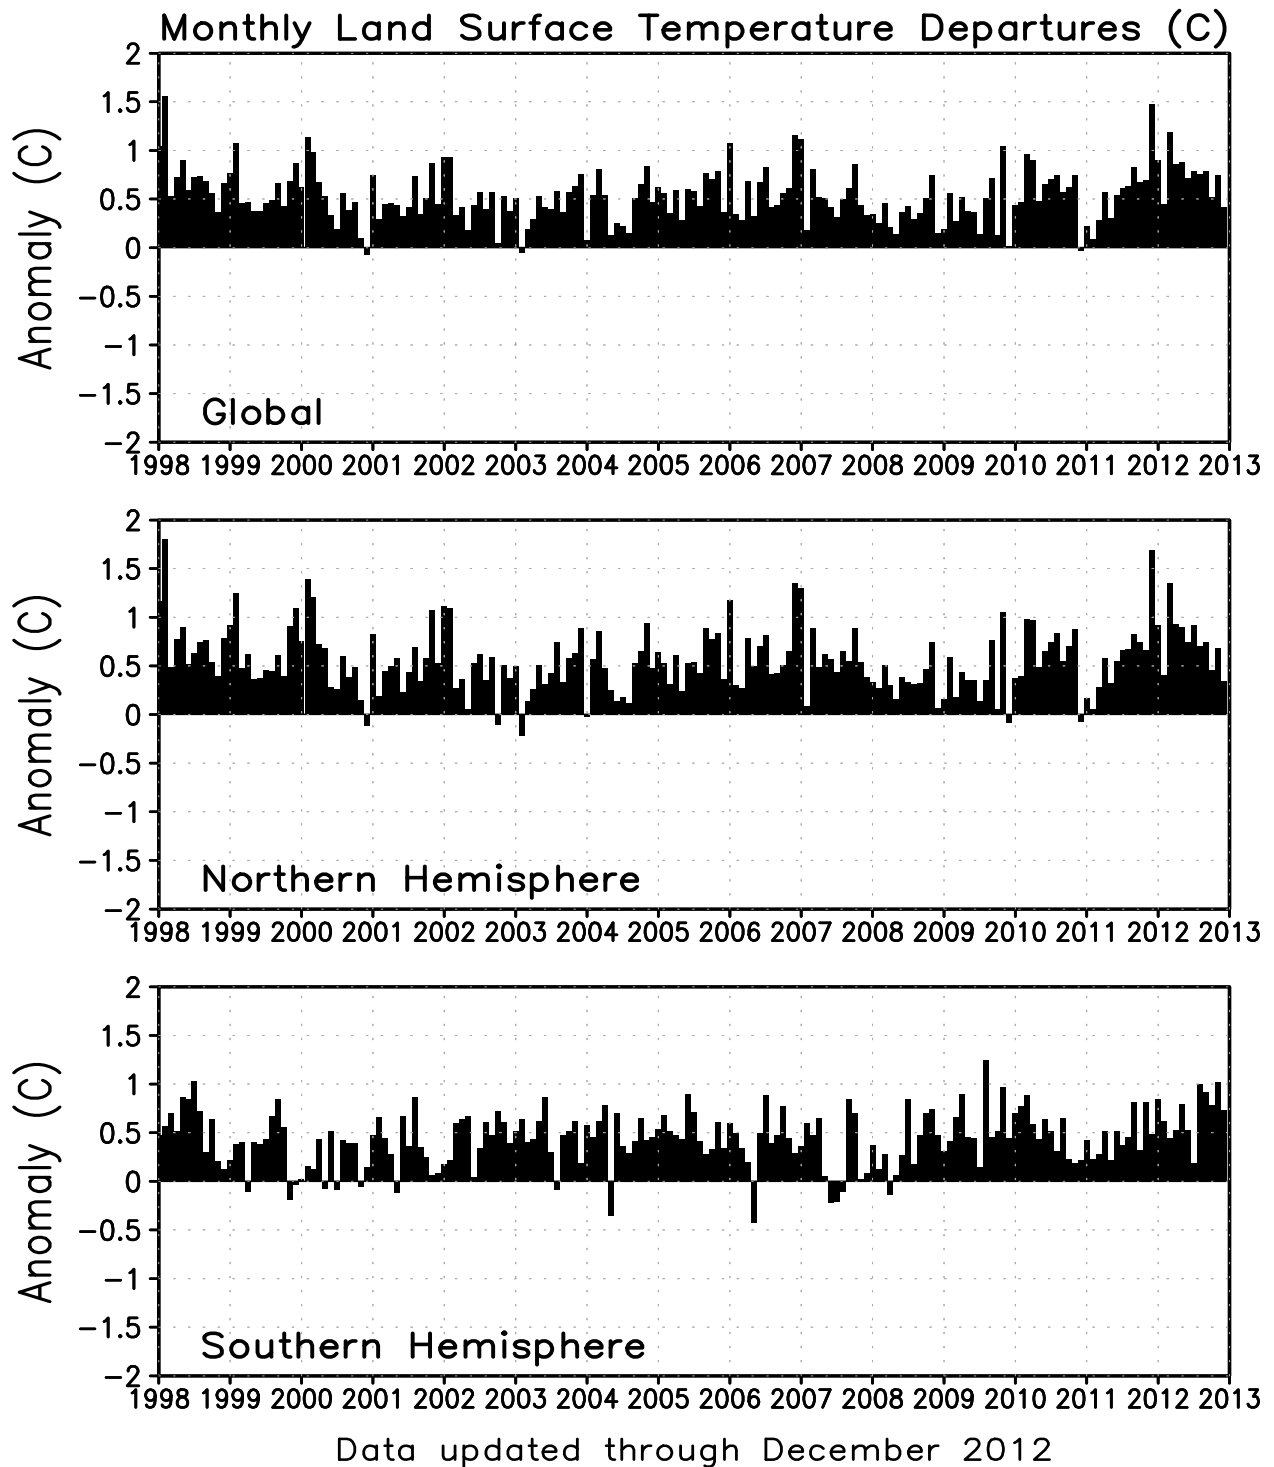

FIGURE E2. Monthly global (top), Northern Hemisphere (middle), and Southern Hemisphere (bottom) surface temperature anomalies (land only, °C) from January 1990 - present, computed as departures from the 1981–2010 base period means.

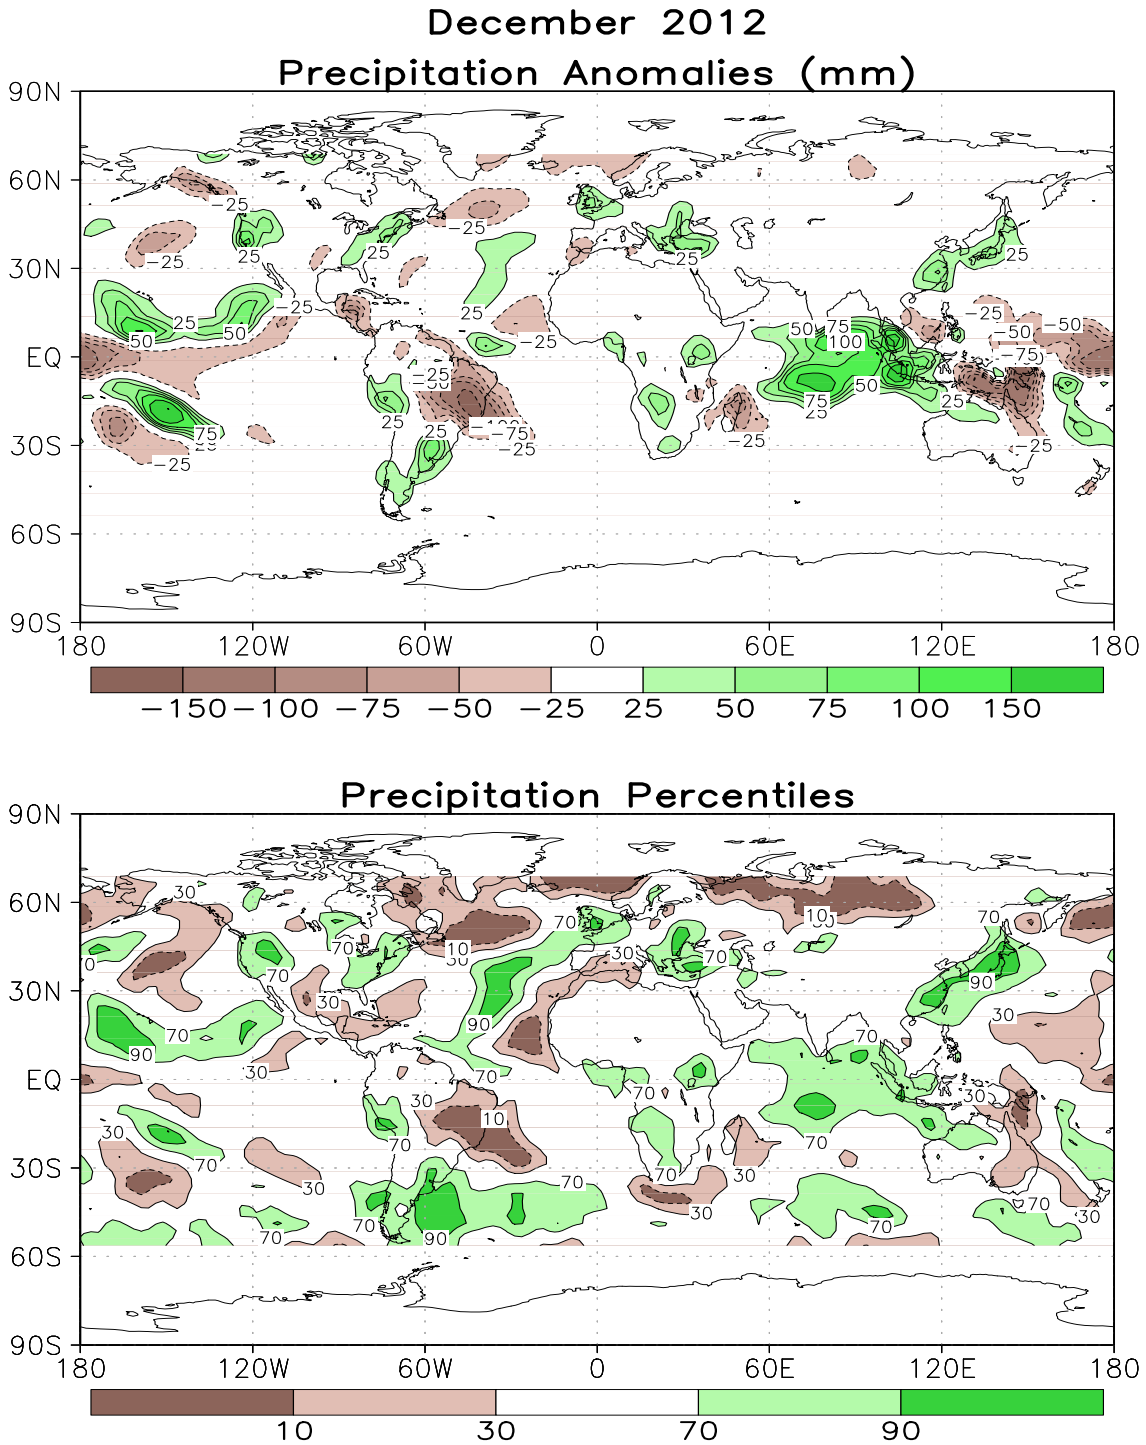

FIGURE E3. Anomalous precipitation (mm, top) and precipitation percentiles based on a Gamma distribution fit to the 1981–2010 base period data (bottom) for DEC 2012. Data are obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, **12**, 3335–3342). Contours are drawn at 200, 100, 50, 25, -25, -50, -100, and -200 mm in top panel. Percentiles are not plotted in regions where mean monthly precipitation is <5mm/month.

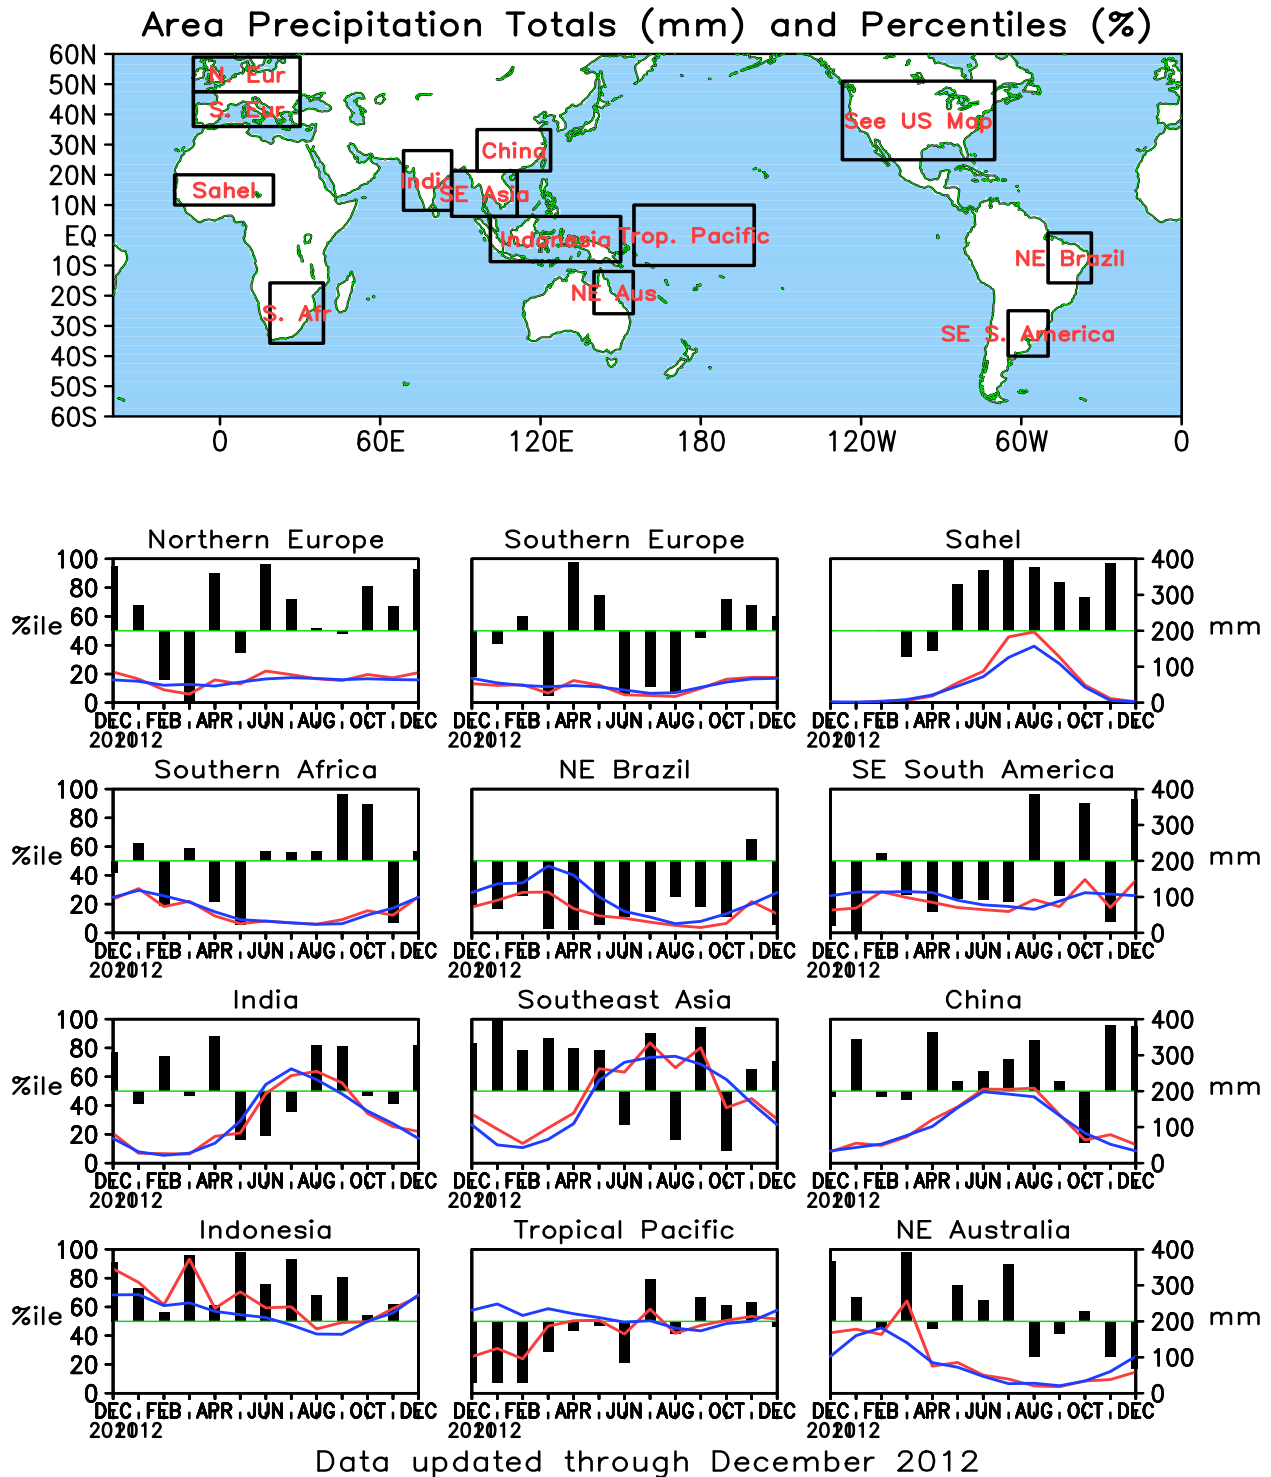

FIGURE E4. Areal estimates of monthly mean precipitation amounts (mm, solid lines) and precipitation percentiles (% , bars) for the most recent 13 months obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, 12, 3335–3342). The monthly precipitation climatology (mm, dashed lines) is from the 1981–2010 base period monthly means. Monthly percentiles are not shown if the monthly mean is less than 5 mm.

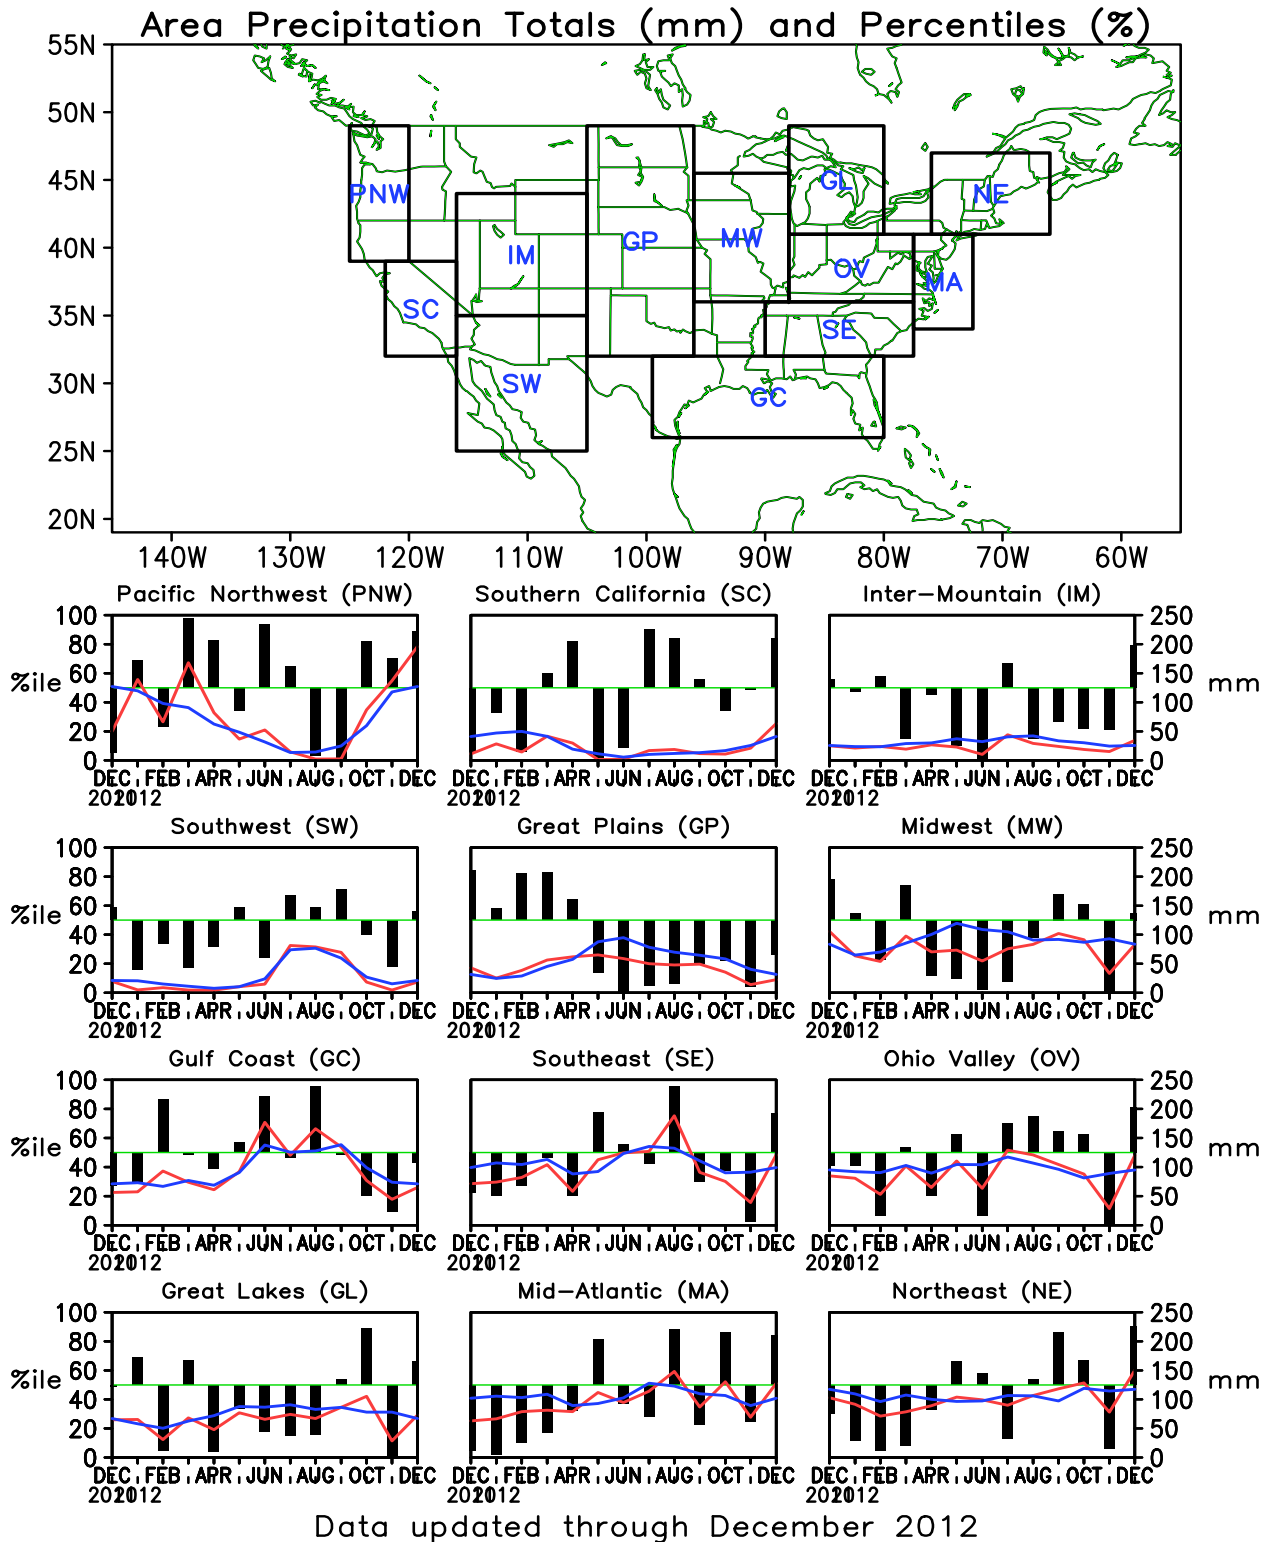

FIGURE E5. Areal estimates of monthly mean precipitation amounts (mm, solid lines) and precipitation percentiles (% , bars) for the most recent 13 months obtained from a merge of raingauge observations and satellite-derived precipitation estimates (Janowiak and Xie 1999, *J. Climate*, 12, 3335–3342). The monthly precipitation climatology (mm, dashed lines) is from the 1981–2010 base period monthly means. Monthly percentiles are not shown if the monthly mean is less than 5 mm.

Monthly Accumulation -- December, 2012

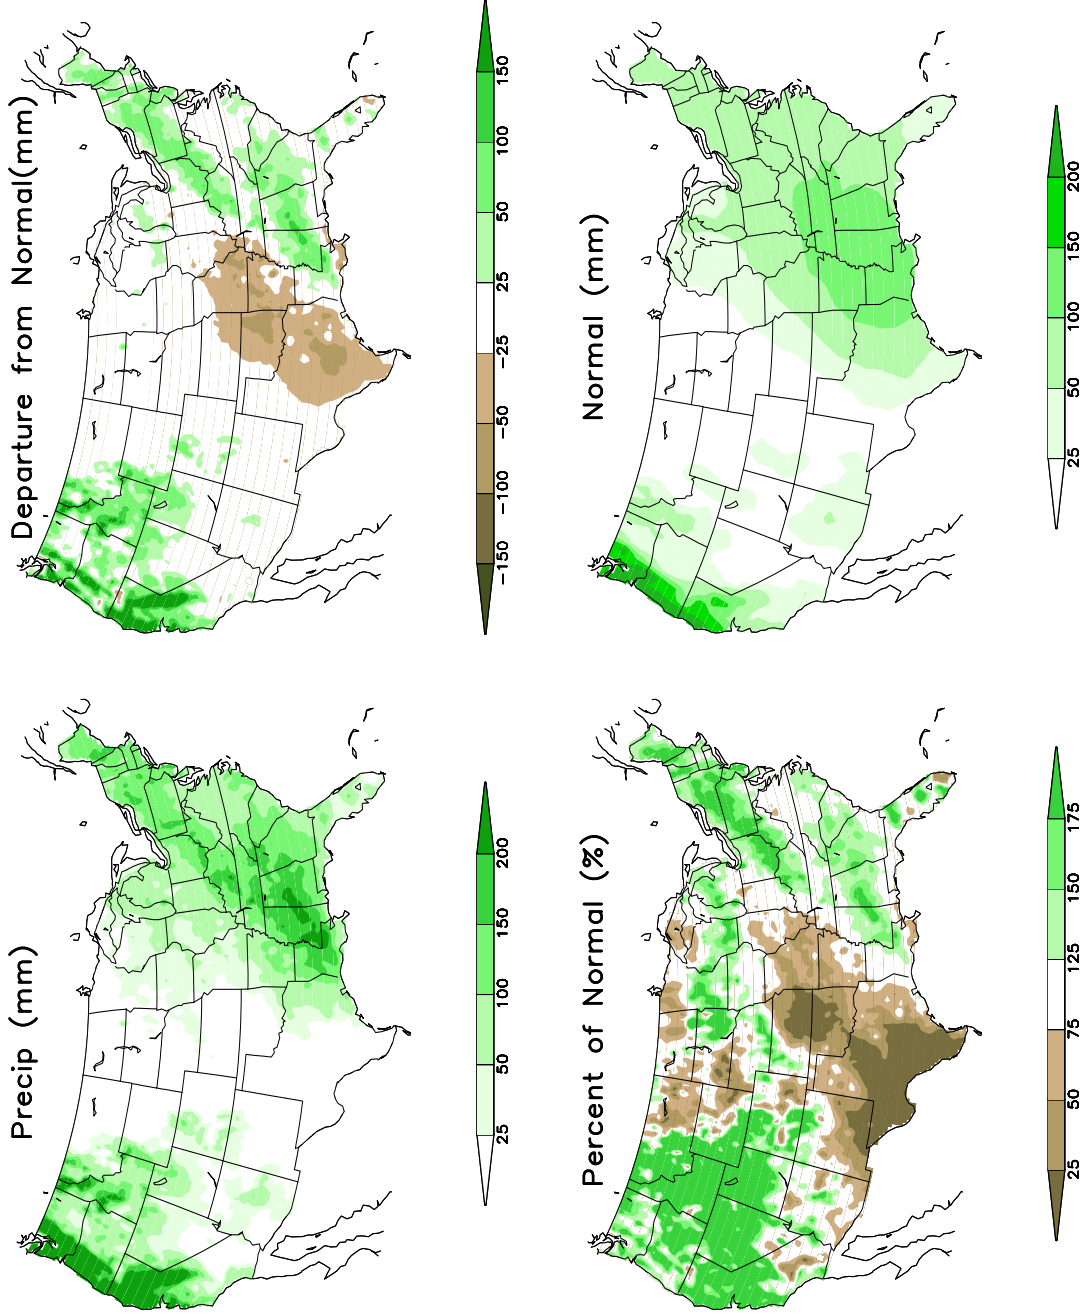

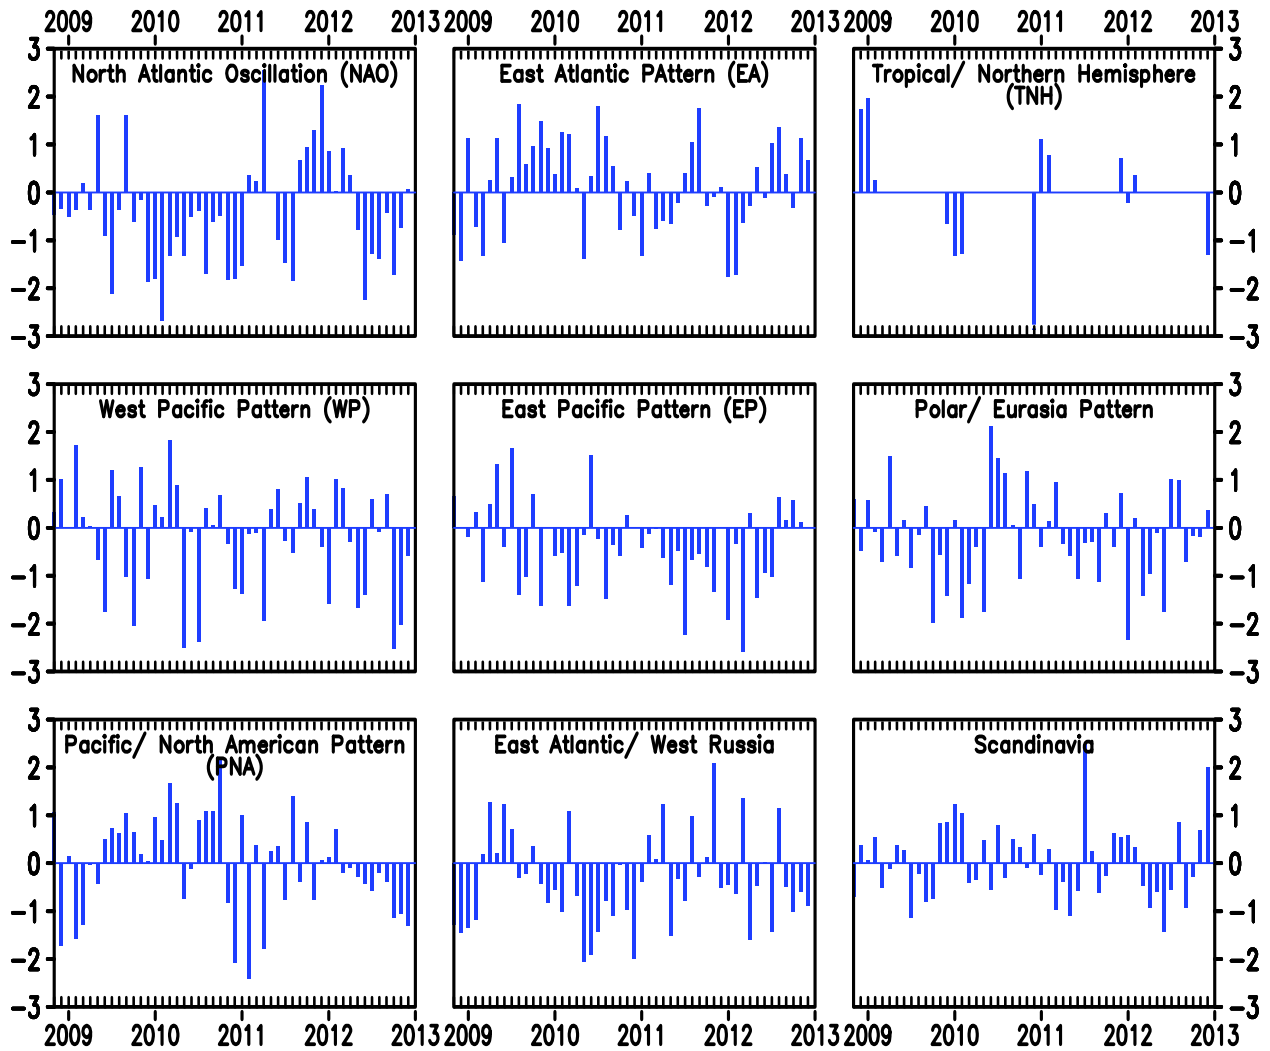

FIGURE E6. Observed precipitation (upper left), departure from average (upper right), percent of average (lower left), and average precipitation (lower right) for DEC 2012. The units are given on each panel. Base period for averages is 1981–2010. Results are based on CPC’s U. S. daily precipitation analysis, which is available at <http://www.cpc.ncep.noaa.gov/products/precip/realtime>.

# Monthly Teleconnection Indices

Data updated through December 2012

FIGURE E7. Standardized monthly Northern Hemisphere teleconnection indices. The teleconnection patterns are calculated from a Rotated Principal Component Analysis (RPCA) applied to monthly standardized 500-hPa height anomalies during the 1981-2010 base period. To obtain these patterns, ten leading un-rotated modes are first calculated for each calendar month by using the monthly height anomaly fields for the three-month period centered on that month: [i.e., The July modes are calculated from the June, July, and August standardized monthly anomalies]. A Varimax spatial rotation of the ten leading un-rotated modes for each calendar month results in 120 rotated modes (12 months x 10 modes per month) that yield ten primary teleconnection patterns. The teleconnection indices are calculated by first projecting the standardized monthly anomalies onto the teleconnection patterns corresponding to that month (eight or nine teleconnection patterns are seen in each calendar month). The indices are then solved for simultaneously using a Least-Squares approach. In this approach, the indices are the solution to the Least-Squares system of equations which explains the maximum spatial structure of the observed height anomaly field during the month. The indices are then standardized for each pattern and calendar month independently. No index value exists when the teleconnection pattern does not appear as one of the ten leading rotated EOF's valid for that month.

December 2012  
500-hPa Height Anomalies: 40°S

FIGURE E18. Southern Hemisphere: Daily 500-hPa height anomalies for DEC 2012 averaged over the 5° latitude band centered on 40°S. Positive values are indicated by solid contours and dark shading. Negative values are indicated by dashed contours and light shading. Contour interval is 60 m. Anomalies are departures from the 1981-2010 base period daily means.

December 2012  
Height Anomalies

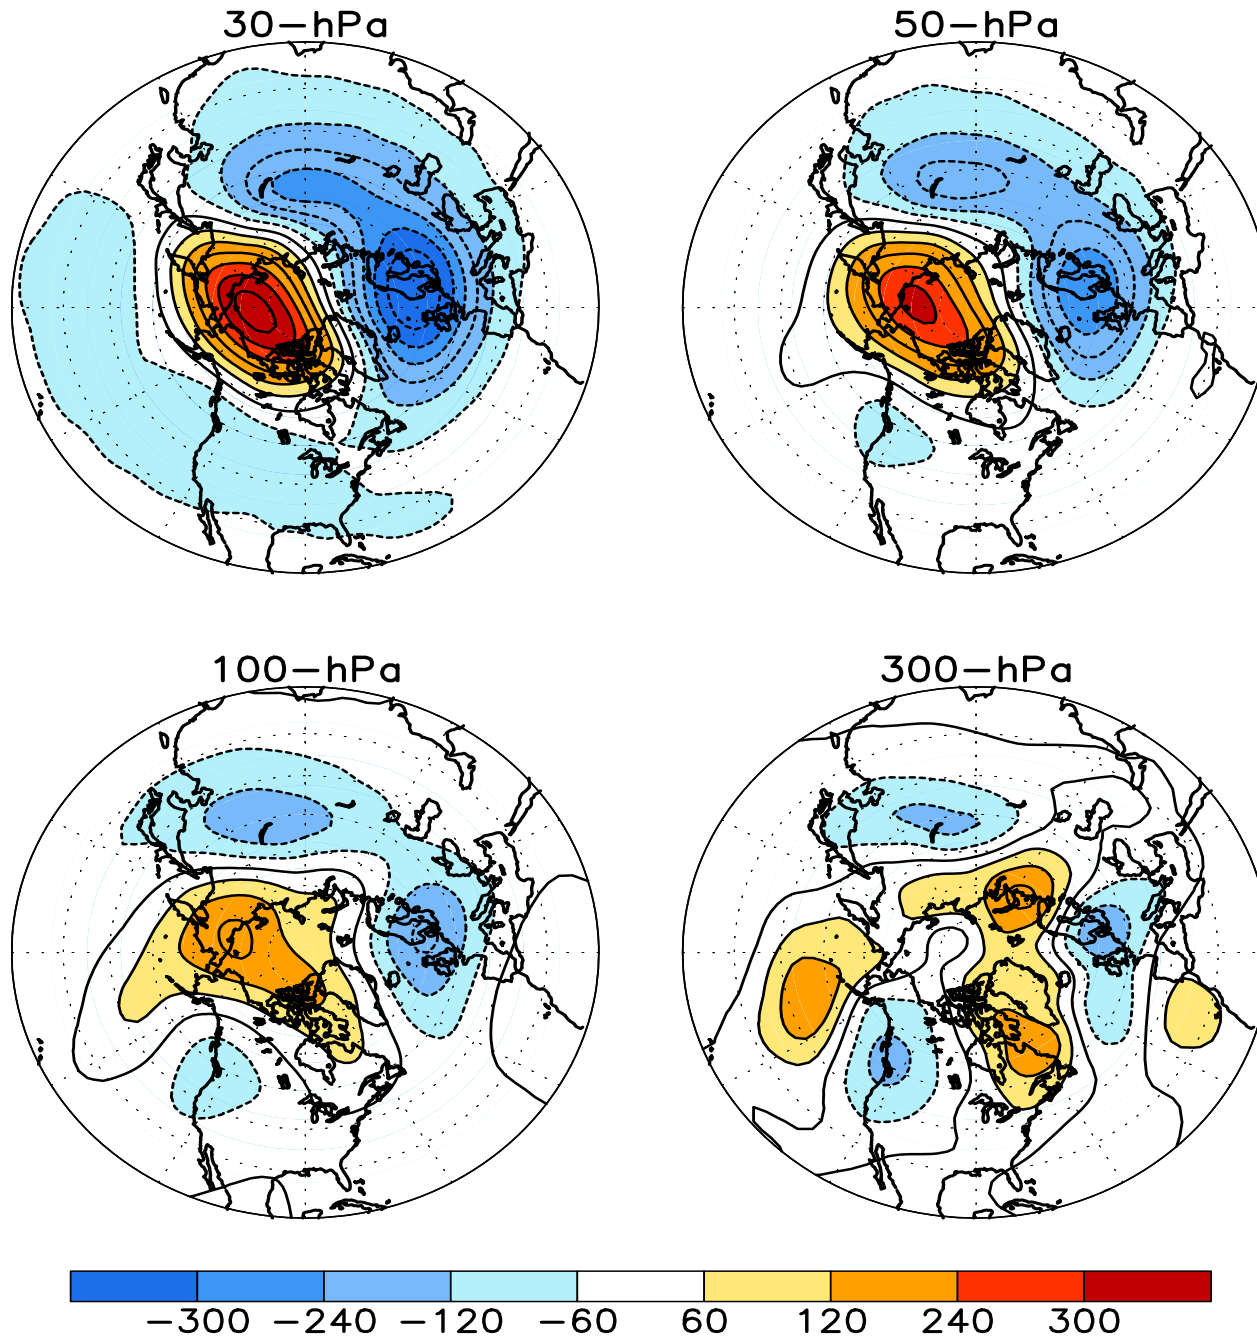

FIGURE S1. Stratospheric height anomalies (m) at selected levels for DEC 2012. Positive values are indicated by solid contours and dark shading. Negative values are indicated by dashed contours and light shading. Contour interval is 60 m. Anomalies are calculated from the 1981-2010 base period means. Winter Hemisphere is shown.

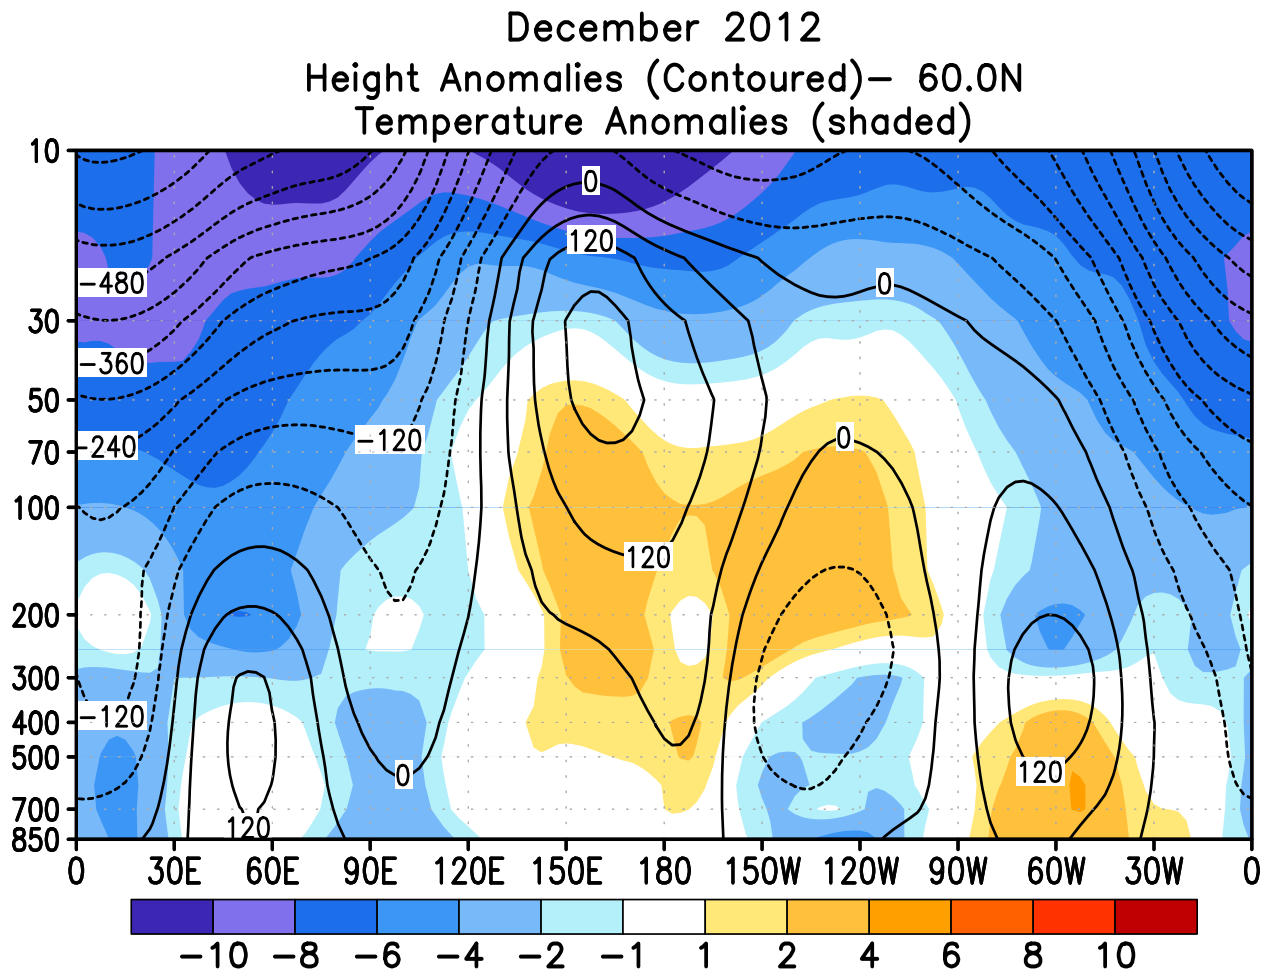

FIGURE S2. Height-longitude sections during DEC 2012 for height anomalies (contour) and temperature anomalies (shaded). In both panels, positive values are indicated by solid contours and dark shading, while negative anomalies are indicated by dashed contours and light shading. Contour interval for height anomalies is 60 m and for temperature anomalies is 2°C. Anomalies are calculated from the 1981-2010 base period monthly means. Winter Hemisphere is shown.

### 50hPa OND Mean Temperature Anomalies

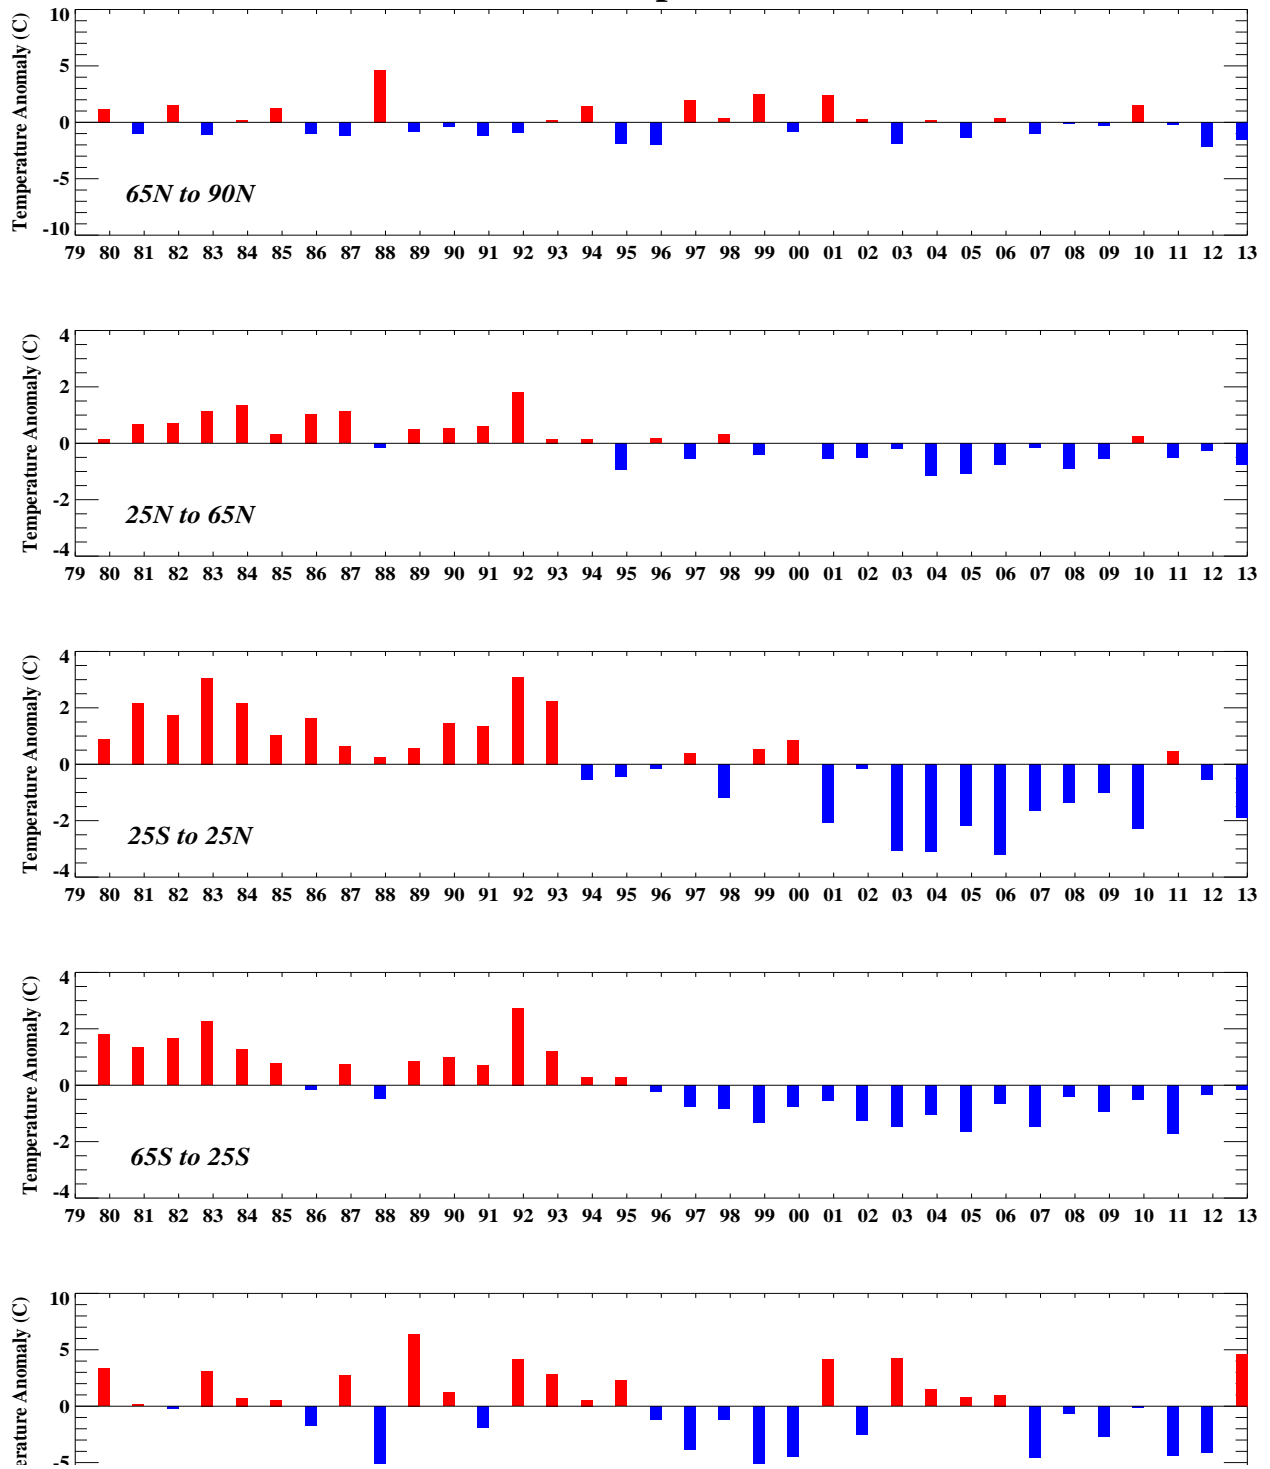

FIGURE S3. Seasonal mean temperature anomalies at 50-hPa for the latitude bands 65°–90°N, 25°–65°N, 25°N–25°S, 25°–65°S, 65°–90°S. The seasonal mean is comprised of the most recent three months. Zonal anomalies are taken from the mean of the entire data set.

### Zonal Mean Temperature for 2011 & 2012

FIGURE S4. Daily mean temperatures at 10-hPa and 2-hPa (thick line) in the region 65°–90°N and 65°–90°S for the past two years. Dashed line depicts the 1981–2010 base period daily mean. Thin solid lines depict the daily extreme maximum and minimum temperatures.

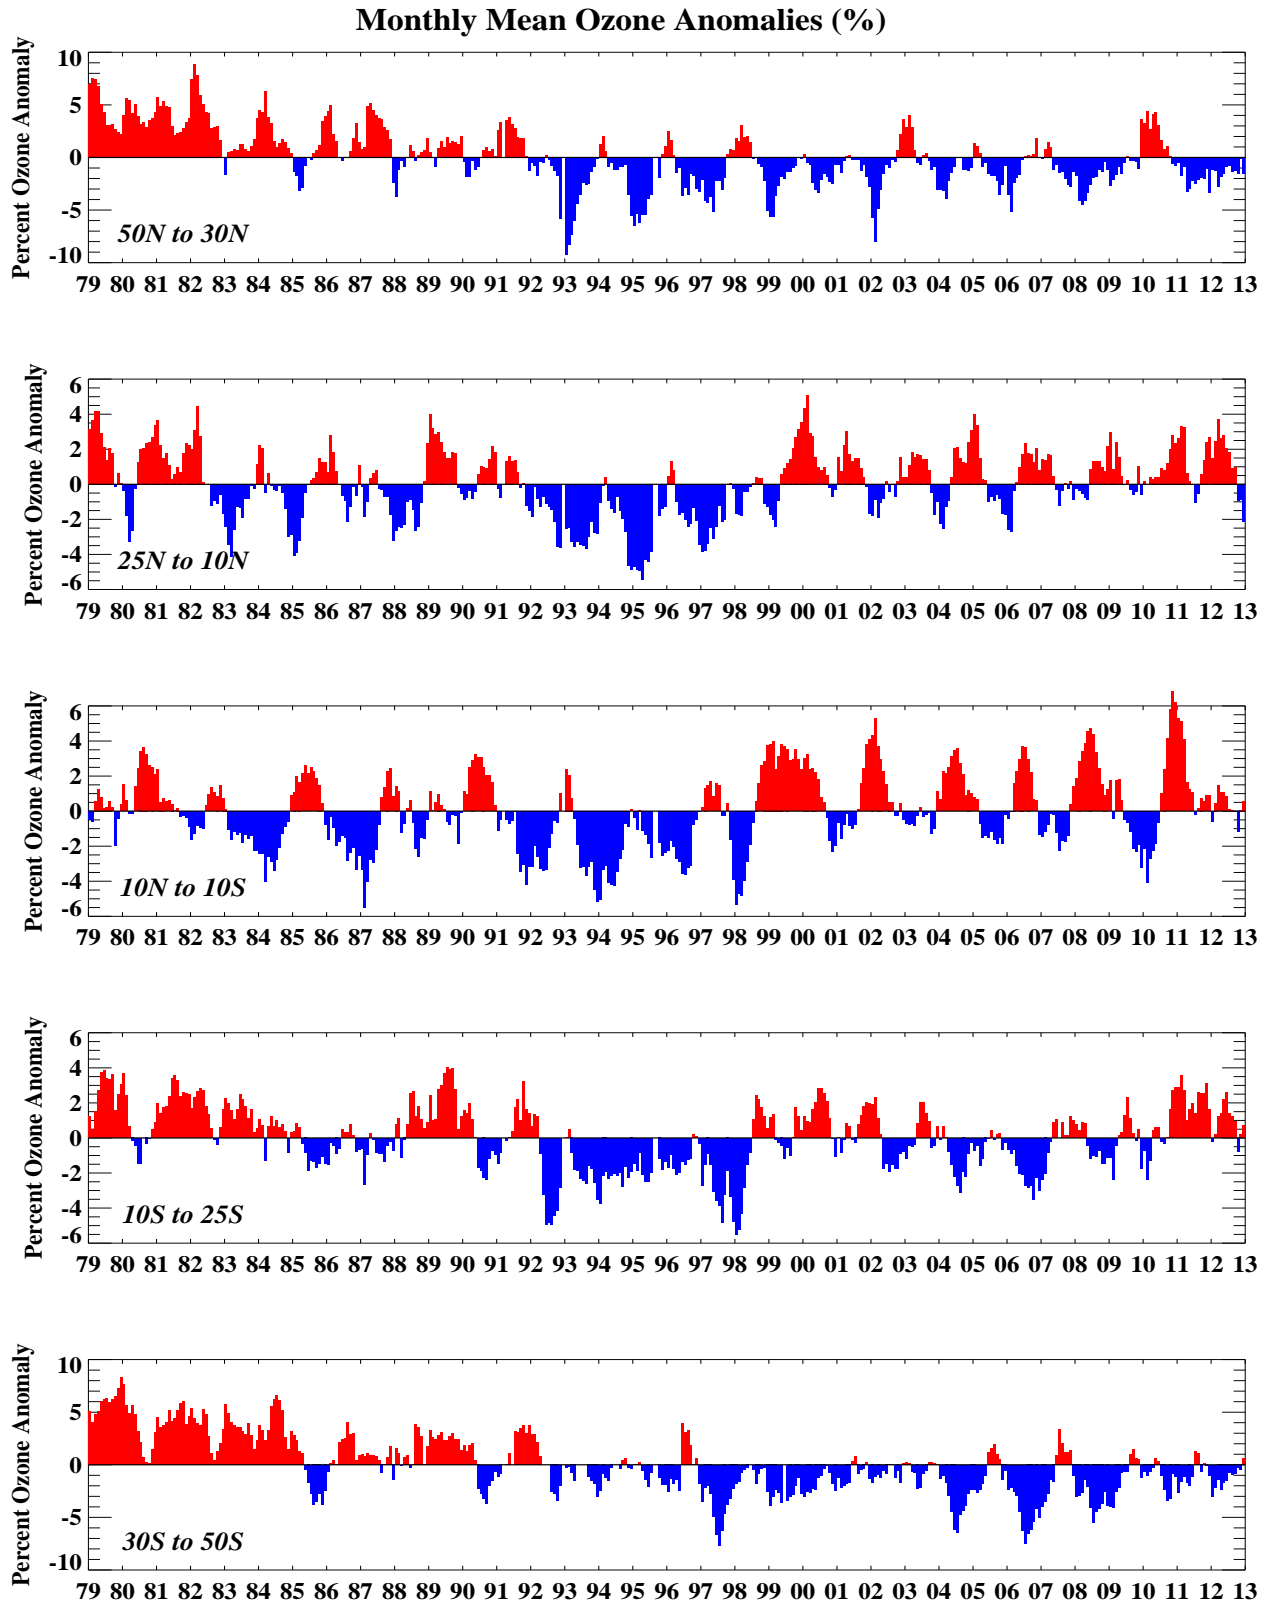

FIGURE S5. Monthly ozone anomalies (percent) from the long term monthly means for five zones: 50N-30N (NH mid-latitudes), 25N-10N (NH tropical surf zone), 10N-10S (Equatorial-QBO zone), 10S-25S (SH tropical surf zone), and 30S-50S (SH mid-latitudes). The long term monthly means are determined from the entire data set

**DECEMBER PERCENT DIFF (2012 - AVG[79-86])**

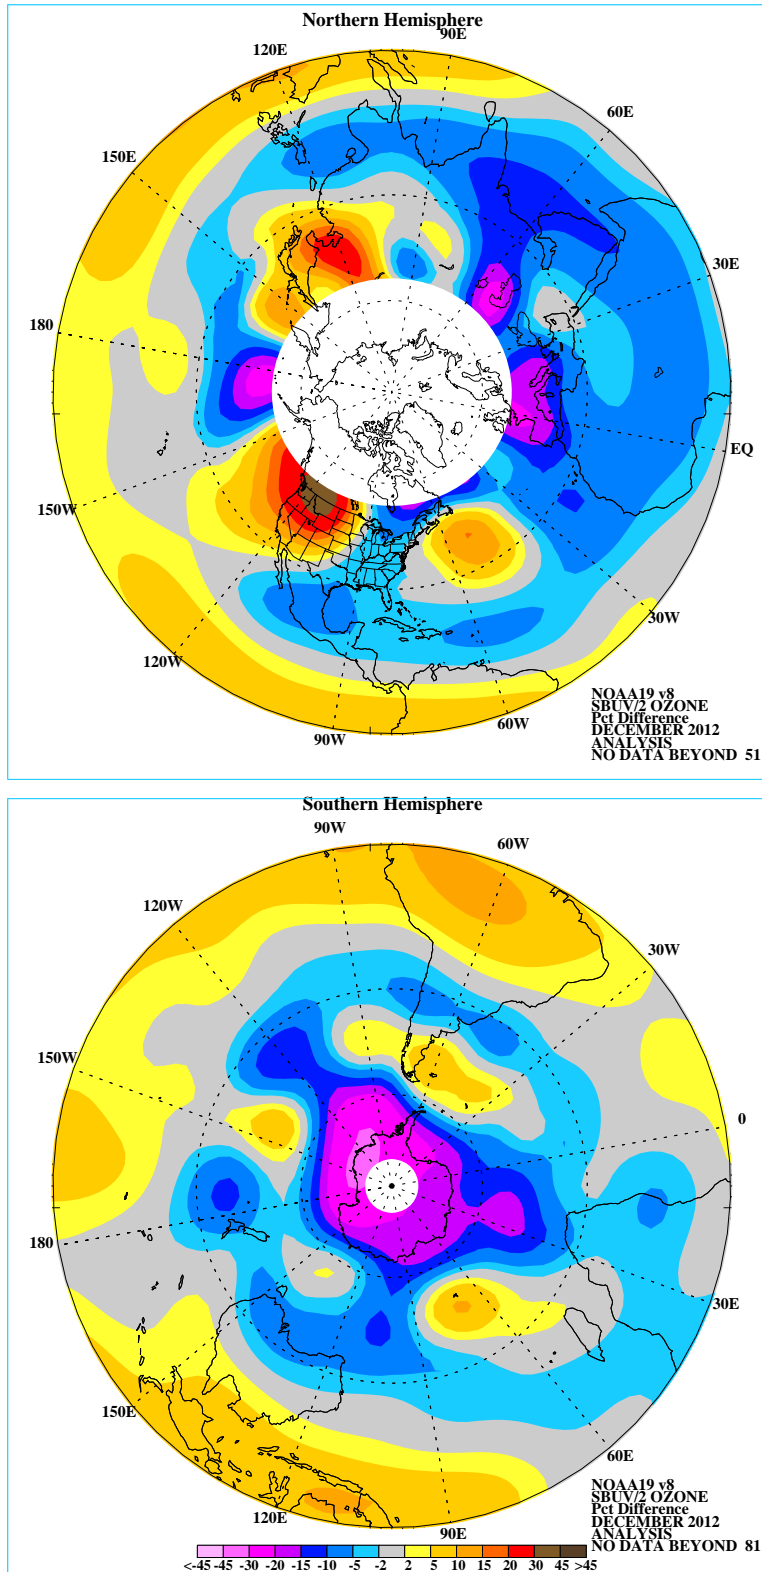

FIGURE S6. Northern (top) and Southern (bottom) Hemisphere total ozone anomaly (percent difference from monthly mean for the period 1979-1986). The region near the winter pole has no SBUV/2 data.

# Fz at 100 hPa (Dec. 2012)

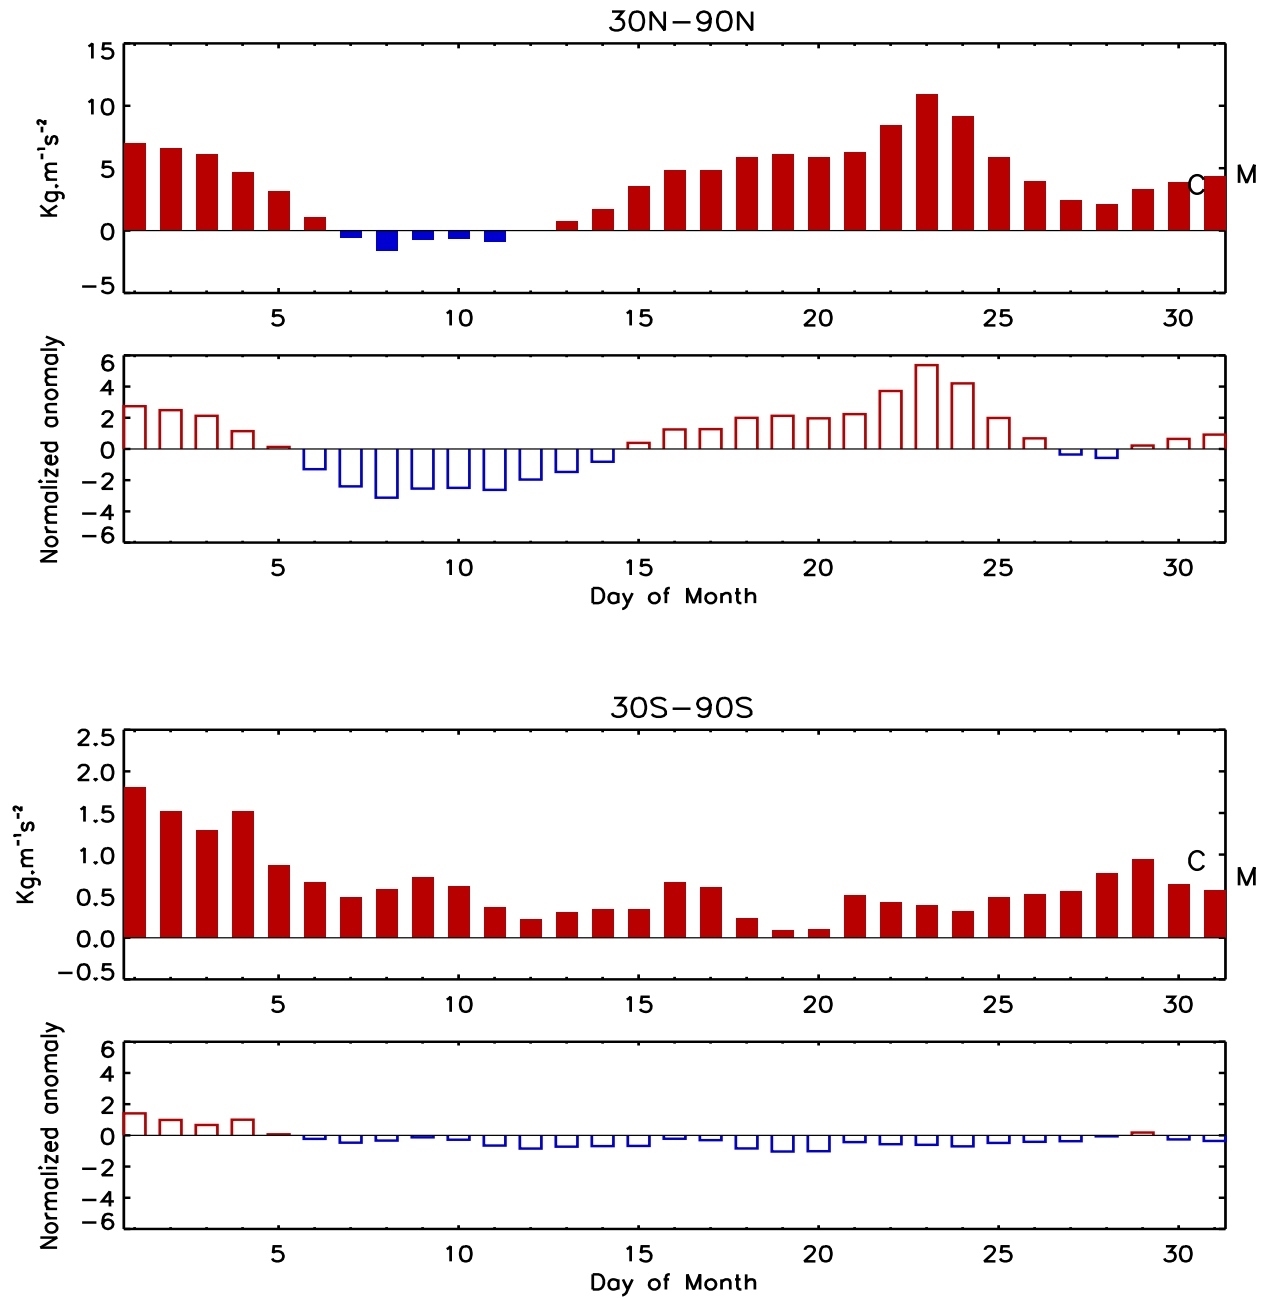

FIGURE S7. Daily vertical component of EP flux (which is proportional to the poleward transport of heat or upward transport of potential energy by planetary wave) at 100 hPa averaged over (top) 30°N–90°N and (bottom) 30°S–90°S for DEC 2012. The EP flux unit ( $\text{kg m}^{-1} \text{s}^{-2}$ ) has been scaled by multiplying a factor of the Brunt Vaisala frequency divided by the Coriolis parameter and the radius of the earth. The letter ‘M’ indicates the current monthly mean value and the letter ‘C’ indicates the climatological mean value. Additionally, the normalized departures from the monthly climatological EP flux values are shown.

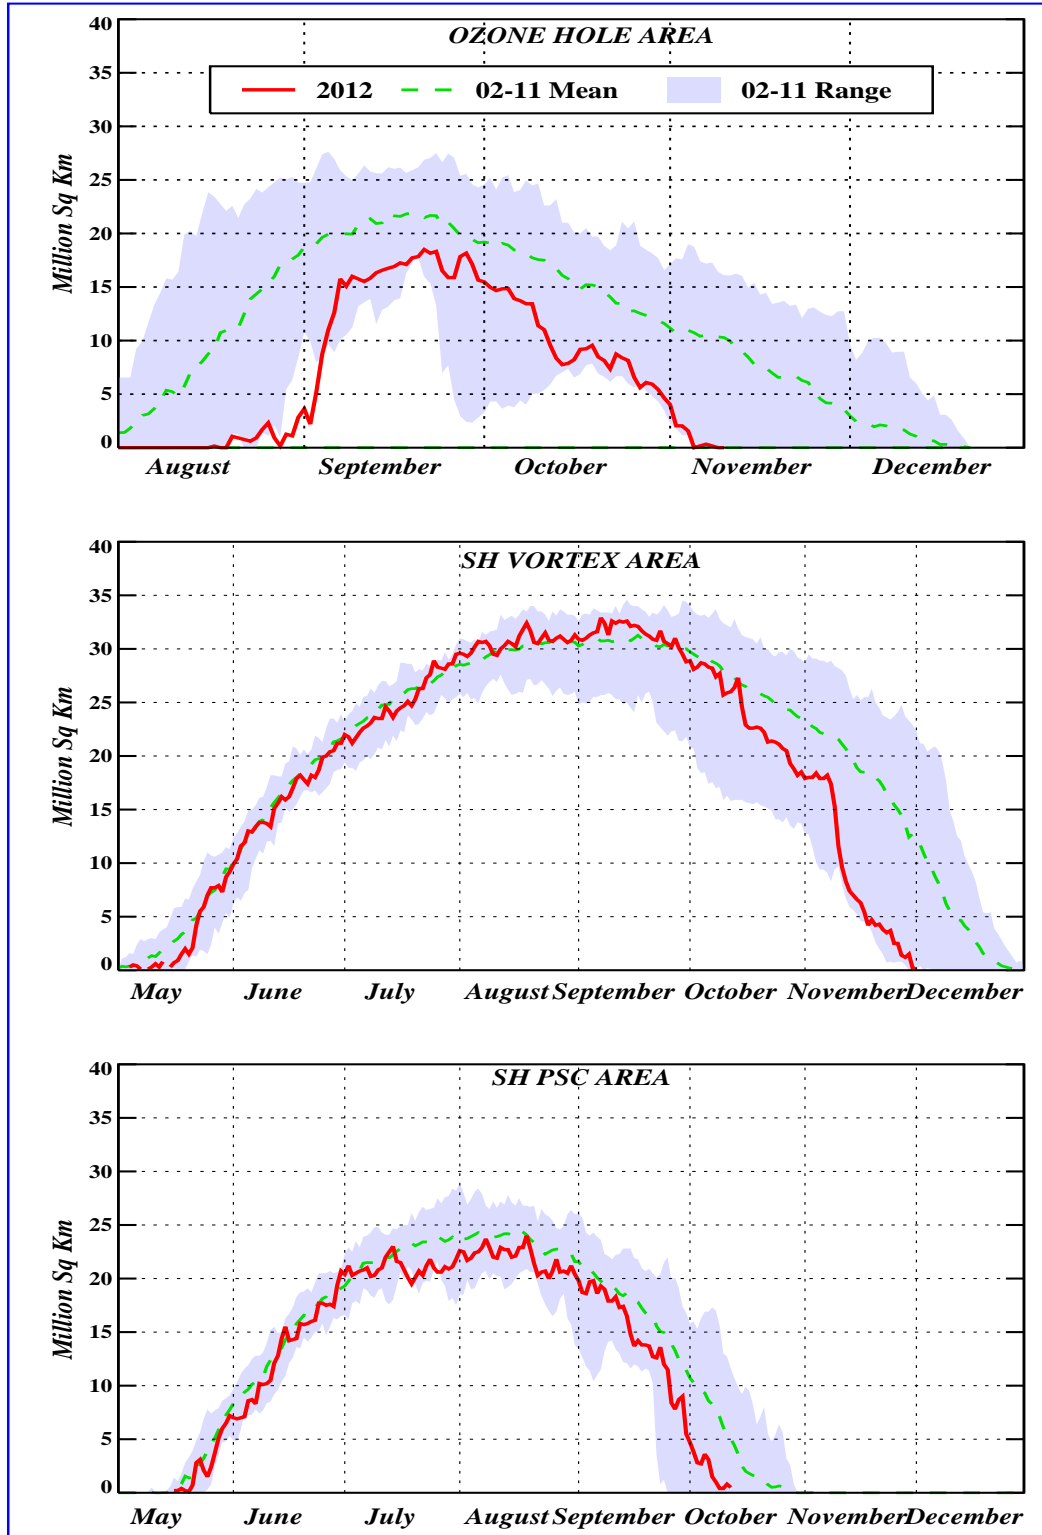

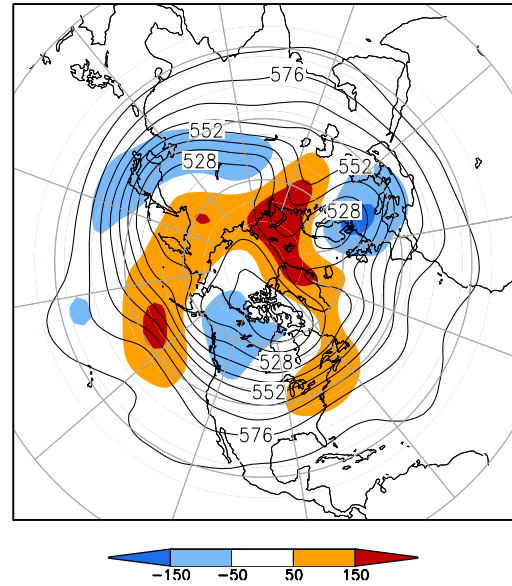

FIGURE S8. Daily time series showing the size of the SH polar vortex (representing the area enclosed by the 32 PVU contour on the 450K isentropic surface), and the areal coverage of temperatures < -78C on the 450K isentropic surface.

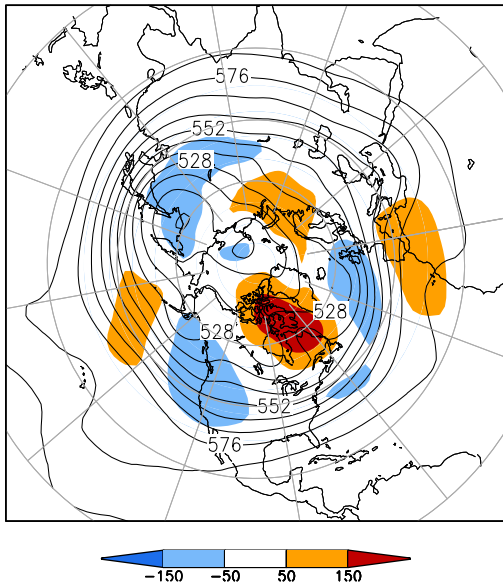

500-hPa Height (dm) & Anomalies (m)  
(Dec 1–15, 2012)

500-hPa Height (dm) & Anomalies (m)  
(Dec 16–31, 2012)

500-hPa Height (dm) & Anomalies (m)  
(Dec 1–31, 2012)

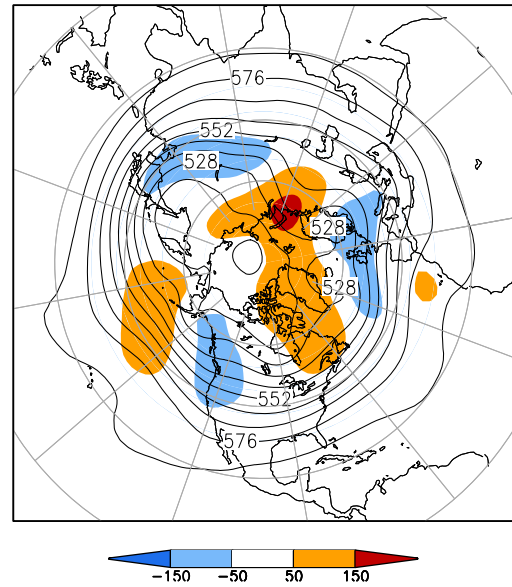

FIGURE A2.1. (a) Daily amplitudes of the Arctic Oscillation (AO) the North Atlantic Oscillation (NAO), and the Pacific-North American (PNA) pattern. The pattern amplitudes for the AO, (NAO, PNA) are calculated by projecting the daily 1000-hPa (500-hPa) height anomaly field onto the leading EOF obtained from standardized time-series of daily 1000-hPa (500-hPa) height for all months of the year. The base period is 1981–2010.

(b-d) Northern Hemisphere mean and anomalous 500-hPa geopotential height (CDAS/Reanalysis) for selected periods during DEC 2012 are shown in the remaining 3 panels. Mean heights are denoted by solid contours drawn at an interval of 8 dam. Dark (light) shading corresponds to anomalies greater than 50 m (less than -50 m). Anomalies are calculated as departures from the 1981-2010 base period daily means.

**SSM/I Snow Cover for Dec 2012  
anomaly based on departure from 1987–2010 baseline**

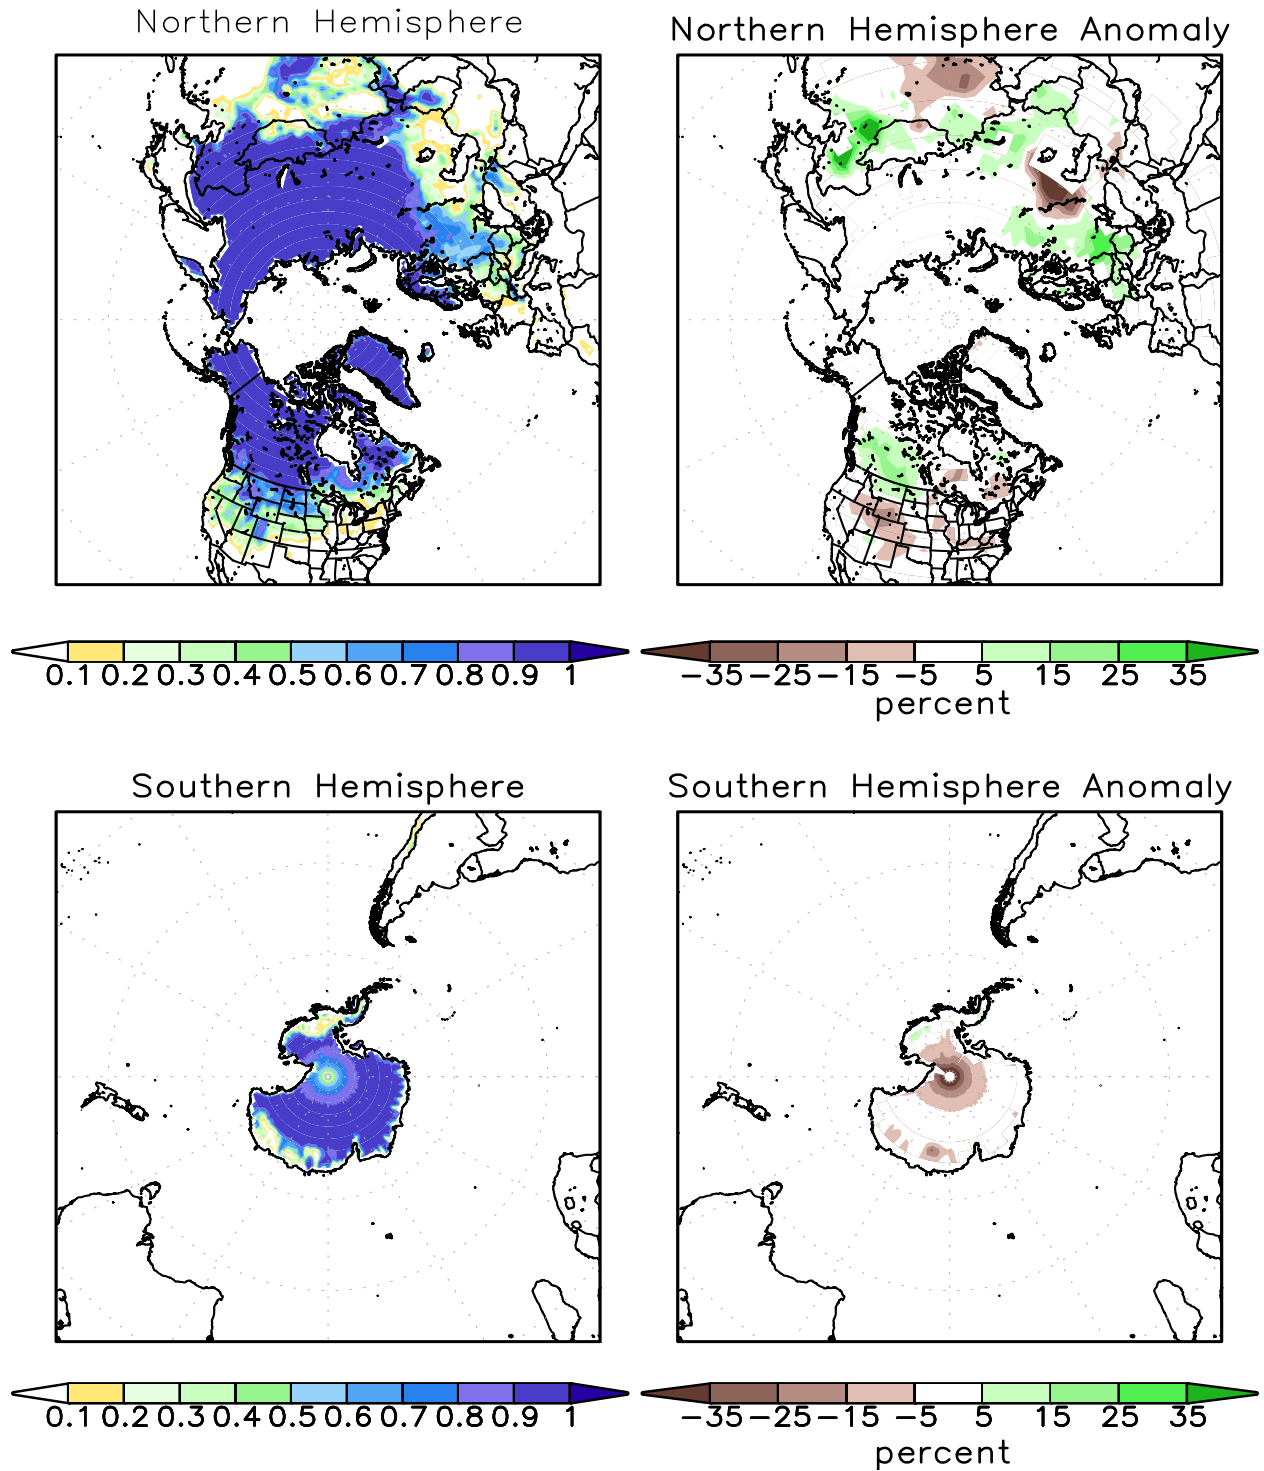

FIGURE A2.2. SSM/I derived snow cover frequency (%) (left) and snow cover anomaly (%) (right) for the month of DEC 2012 based on 1987 - 2010 base period for the Northern Hemisphere (top) and Southern Hemisphere (bottom). It is generated using the algorithm described by Ferraro et. al, 1996, Bull. Amer. Meteor. Soc., vol 77, 891-905.
